# CSCI x760 - Computer Networks Spring 2016

Instructor: Prof. Roberto Perdisci  
[perdisci@cs.uga.edu](mailto:perdisci@cs.uga.edu)

*These slides are adapted from the textbook slides by J.F. Kurose and K.W. Ross*

# Chapter 5: The Data Link Layer

---

## Our goals:

- ▶ understand principles behind data link layer services:
  - ▶ error detection, correction
  - ▶ sharing a broadcast channel: multiple access
  - ▶ link layer addressing
  - ▶ reliable data transfer, flow control: *done!*
- ▶ instantiation and implementation of various link layer technologies

# Link Layer

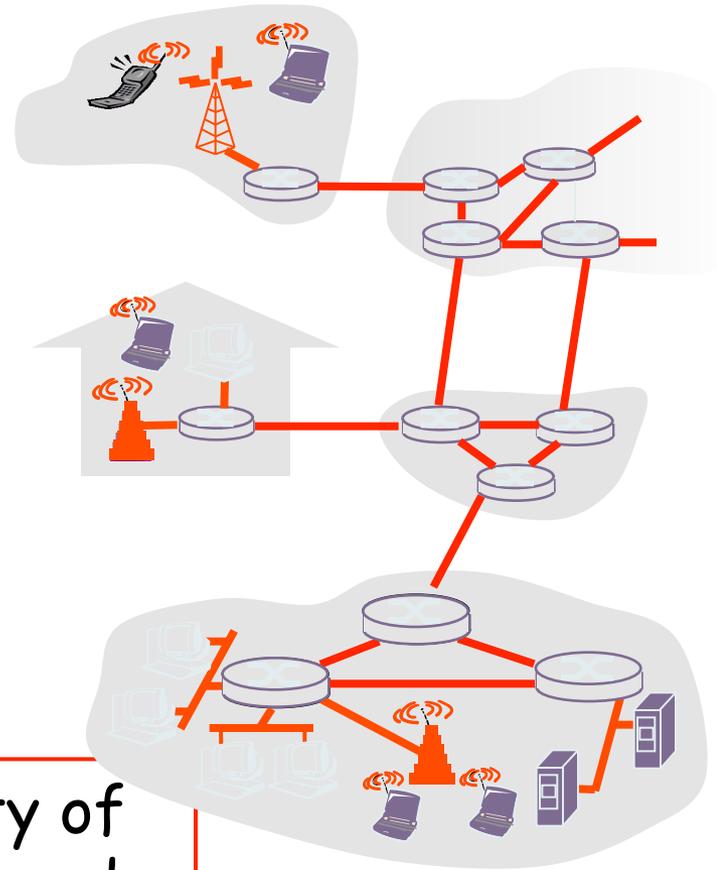

---

- ▶ **5.1 Introduction and services**
- ▶ 5.2 Error detection and correction
- ▶ 5.3 Multiple access protocols
- ▶ 5.4 Link-layer Addressing
- ▶ 5.5 Ethernet
- ▶ 5.6 Link-layer switches
- ▶ 5.7 PPP
- ▶ 5.8 Link virtualization: MPLS
- ▶ 5.9 A day in the life of a web request

# Link Layer: Introduction

## Some terminology:

- ▶ hosts and routers are **nodes**
- ▶ communication channels that connect adjacent nodes along communication path are **links**
  - ▶ wired links
  - ▶ wireless links
  - ▶ LANs
- ▶ layer-2 packet is a **frame**, encapsulates datagram

**data-link layer** has responsibility of transferring datagram from one node to adjacent node over a link

# Link layer: context

---

- ▶ datagram transferred by different link protocols over different links:
  - ▶ e.g., Ethernet on first link, frame relay on intermediate links, 802.11 on last link
- ▶ each link protocol provides different services
  - ▶ e.g., may or may not provide rdt over link

## transportation analogy

- ▶ trip from Princeton to Lausanne
  - ▶ limo: Princeton to JFK
  - ▶ plane: JFK to Geneva
  - ▶ train: Geneva to Lausanne
- ▶ tourist = **datagram**
- ▶ transport segment = **communication link**
- ▶ transportation mode = **link layer protocol**
- ▶ travel agent = **routing algorithm**

# Link Layer Services

---

- ▶ *framing, link access:*
  - ▶ encapsulate datagram into frame, adding header, trailer
  - ▶ channel access if shared medium
  - ▶ “MAC” addresses used in frame headers to identify source, dest
    - ▶ different from IP address!
- ▶ *reliable delivery between adjacent nodes*
  - ▶ we learned how to do this already (chapter 3)!
  - ▶ seldom used on low bit-error link (fiber, some twisted pair)
  - ▶ wireless links: high error rates
    - ▶ Q: why both link-level and end-end reliability?

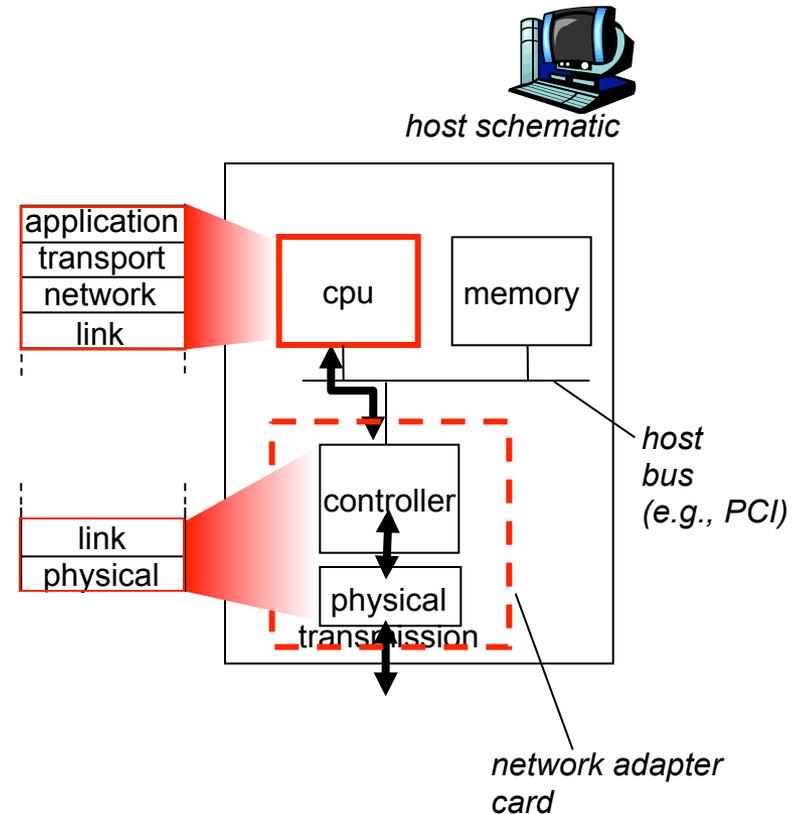

# Link Layer Services (more)

---

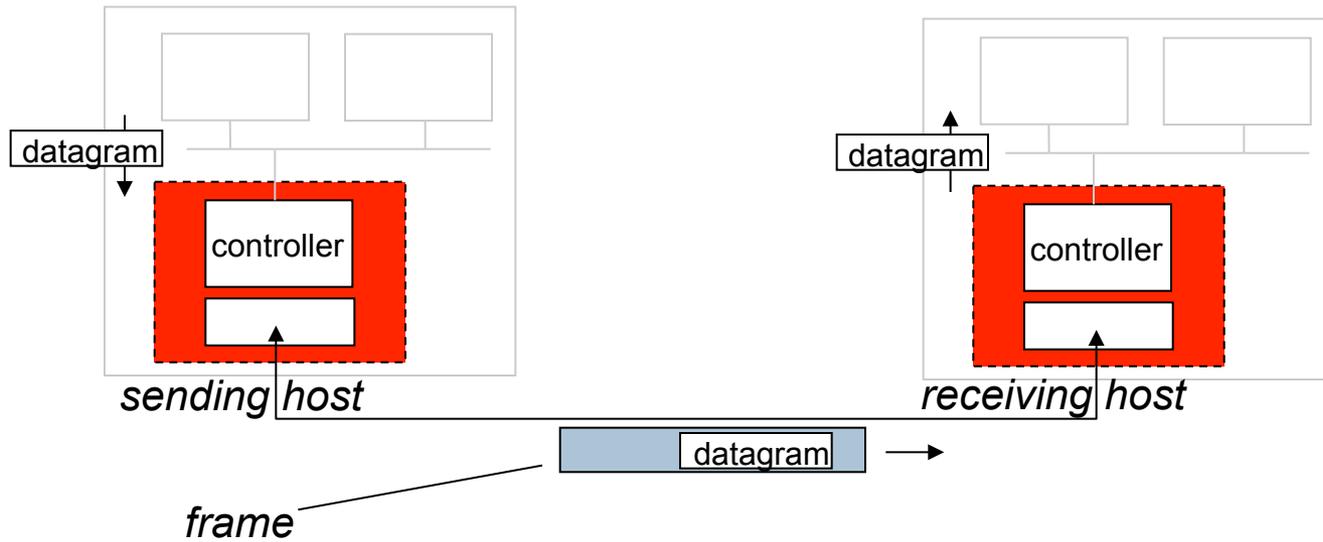

- ▶ **flow control:**
  - ▶ pacing between adjacent sending and receiving nodes
- ▶ **error detection:**
  - ▶ errors caused by signal attenuation, noise.
  - ▶ receiver detects presence of errors:
    - ▶ signals sender for retransmission or drops frame
- ▶ **error correction:**
  - ▶ receiver identifies *and corrects* bit error(s) without resorting to retransmission
- ▶ **half-duplex and full-duplex**
  - ▶ with half duplex, nodes at both ends of link can transmit, but not at same time

# Where is the link layer implemented?

- ▶ in each and every host
- ▶ link layer implemented in “adaptor” (aka *network interface card* NIC)
  - ▶ Ethernet card, PCMCIA card, 802.11 card
  - ▶ implements link, physical layer
- ▶ attaches into host’s system buses
- ▶ combination of hardware, software, firmware

# Adaptors Communicating

## ▶ sending side:

- ▶ encapsulates datagram in frame
- ▶ adds error checking bits, rdt, flow control, etc.

## ▶ receiving side

- ▶ looks for errors, rdt, flow control, etc
- ▶ extracts datagram, passes to upper layer at receiving side

# Link Layer

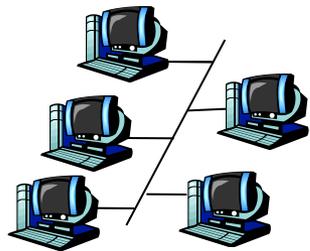

---

- ▶ 5.1 Introduction and services
- ▶ 5.2 Error detection and correction
- ▶ **5.3 Multiple access protocols**
- ▶ 5.4 Link-layer Addressing
- ▶ 5.5 Ethernet
- ▶ 5.6 Link-layer switches
- ▶ 5.7 PPP
- ▶ 5.8 Link virtualization: MPLS
- ▶ 5.9 A day in the life of a web request

# Multiple Access Links and Protocols

Two types of “links”:

- ▶ point-to-point
  - ▶ PPP for dial-up access
  - ▶ point-to-point link between Ethernet switch and host
- ▶ **broadcast** (shared wire or medium)
  - ▶ old-fashioned Ethernet
  - ▶ upstream HFC
  - ▶ 802.11 wireless LAN

shared wire (e.g.,  
cabled Ethernet)

shared RF  
(e.g., 802.11 WiFi)

shared RF  
(satellite)

humans at a  
cocktail party  
(shared air, acoustical)

# Multiple Access protocols

---

- ▶ single shared broadcast channel
- ▶ two or more simultaneous transmissions by nodes: interference
  - ▶ **collision** if node receives two or more signals at the same time

## multiple access protocol

- ▶ distributed algorithm that determines how nodes share channel, i.e., determine when node can transmit
- ▶ communication about channel sharing must use channel itself!
  - ▶ no out-of-band channel for coordination

# Ideal Multiple Access Protocol

---

## Broadcast channel of rate $R$ bps

1. when one node wants to transmit, it can send at rate  $R$ .
2. when  $M$  nodes want to transmit, each can send at average rate  $R/M$
3. fully decentralized:
  - ▶ no special node to coordinate transmissions
  - ▶ no synchronization of clocks, slots
4. simple

# MAC Protocols: a taxonomy

---

MAC = Medium Access Control

Three broad classes:

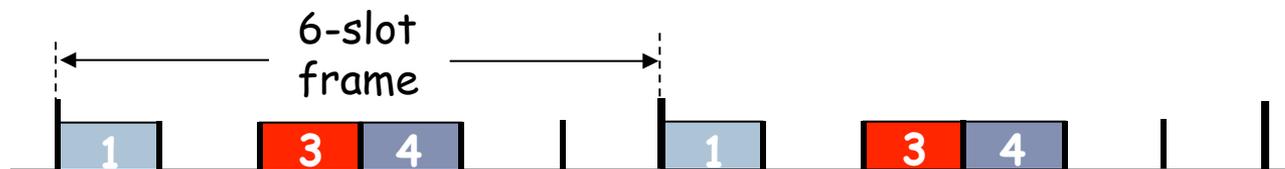

- ▶ **Channel Partitioning**
  - ▶ divide channel into smaller “pieces” (time slots, frequency, code)
  - ▶ allocate piece to node for exclusive use
- ▶ **Random Access**
  - ▶ channel not divided, allow collisions
  - ▶ “recover” from collisions
- ▶ **“Taking turns”**
  - ▶ nodes take turns, but nodes with more to send can take longer turns

# Channel Partitioning MAC protocols: TDMA

---

## TDMA: time division multiple access

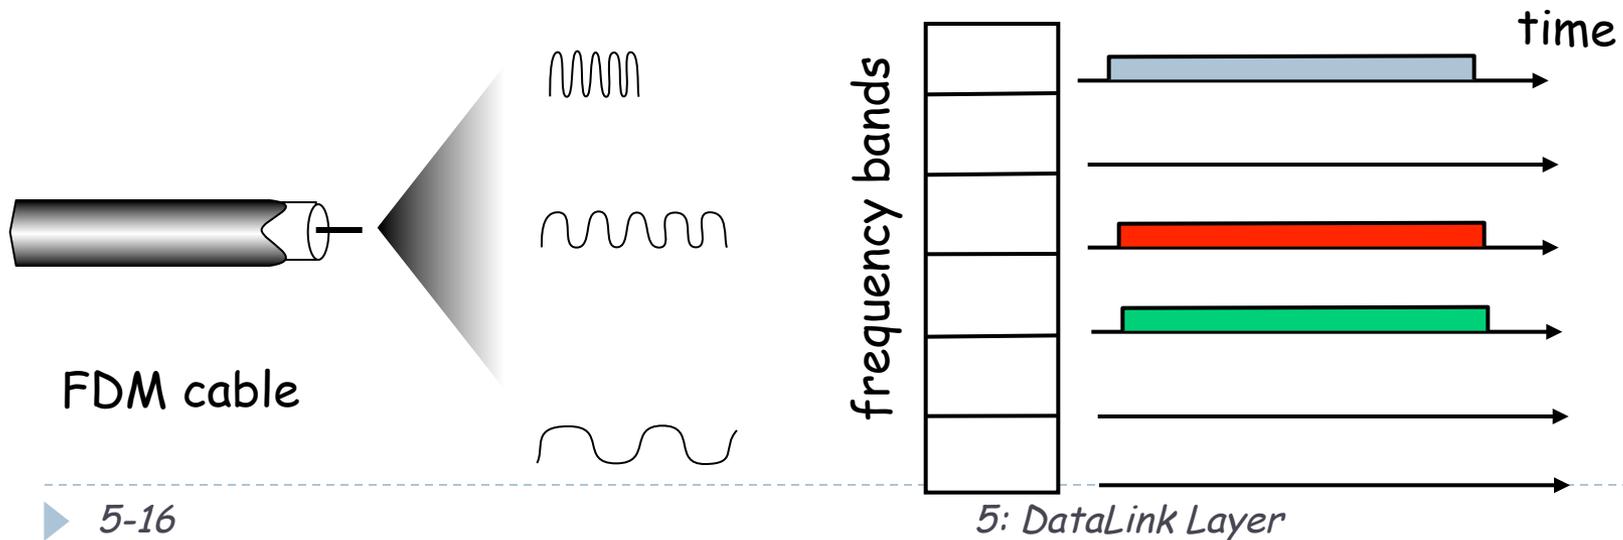

- ▶ access to channel in "rounds"
- ▶ each station gets fixed length slot (length = pkt trans time) in each round
- ▶ unused slots go idle
- ▶ example: 6-station LAN, 1,3,4 have pkt, slots 2,5,6 idle

# Channel Partitioning MAC protocols: FDMA

## FDMA: frequency division multiple access

- ▶ channel spectrum divided into frequency bands
- ▶ each station assigned fixed frequency band
- ▶ unused transmission time in frequency bands go idle
- ▶ example: 6-station LAN, 1,3,4 have pkt, frequency bands 2,5,6 idle

# Random Access Protocols

---

- ▶ When node has packet to send
  - ▶ transmit at full channel data rate  $R$ .
  - ▶ no *a priori* coordination among nodes
- ▶ two or more transmitting nodes → “collision”,
- ▶ **random access MAC protocol** specifies:
  - ▶ how to detect collisions
  - ▶ how to recover from collisions (e.g., via delayed retransmissions)
- ▶ **Examples of random access MAC protocols:**
  - ▶ slotted ALOHA
  - ▶ ALOHA
  - ▶ CSMA, CSMA/CD, CSMA/CA

# Slotted ALOHA

---

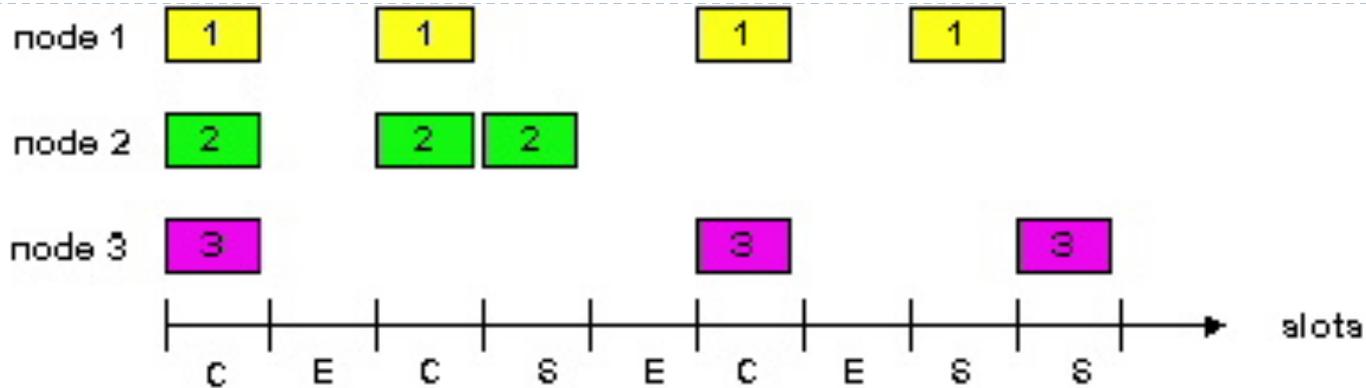

## Assumptions:

- ▶ all frames same size
- ▶ time divided into equal size slots (time to transmit 1 frame)
- ▶ nodes start to transmit only slot beginning
- ▶ nodes are synchronized
- ▶ if 2 or more nodes transmit in slot, all nodes detect collision

## Operation:

- ▶ when node obtains fresh frame, transmits in next slot
  - ▶ *if no collision*: node can send new frame in next slot
  - ▶ *if collision*: node retransmits frame in each subsequent slot with prob.  $p$  until success

# Slotted ALOHA

## Pros

- ▶ single active node can continuously transmit at full rate of channel
- ▶ highly decentralized: only slots in nodes need to be in sync
- ▶ simple

## Cons

- ▶ collisions, wasting slots
- ▶ idle slots
- ▶ nodes may be able to detect collision in less than time to transmit packet
- ▶ clock synchronization

# Slotted Aloha efficiency

**Efficiency** : long-run fraction of successful slots (many nodes, all with many frames to send)

- ▶ *suppose*:  $N$  nodes with many frames to send, each transmits in slot with probability  $p$
- ▶ prob that given node has success in a slot =  $p(1-p)^{N-1}$
- ▶ prob that *any* node has a success =  $Np(1-p)^{N-1}$

- ▶ max efficiency: find  $p^*$  that maximizes  $Np(1-p)^{N-1}$
- ▶ for many nodes, take limit of  $Np^*(1-p^*)^{N-1}$  as  $N$  goes to infinity, gives:

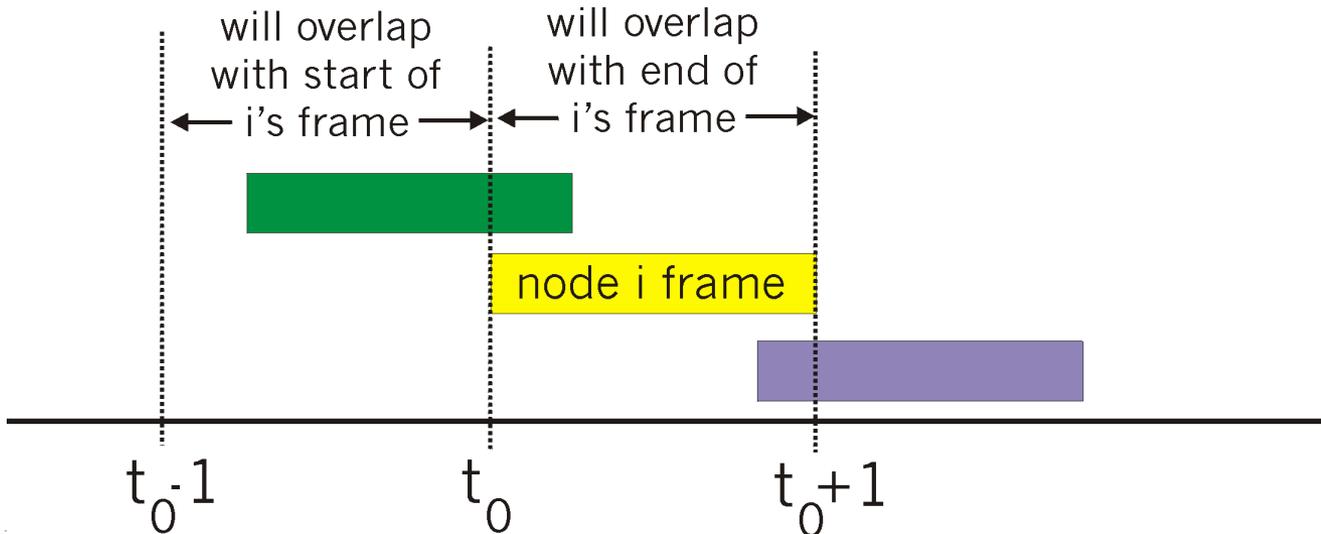

Max efficiency =  $1/e = .37$

***At best:*** channel used for useful transmissions 37% of time!

# Pure (unslotted) ALOHA

- ▶ unslotted Aloha: simpler, no synchronization
- ▶ when frame first arrives
  - ▶ transmit immediately
- ▶ collision probability increases:
  - ▶ frame sent at  $t_0$  collides with other frames sent in  $[t_0-1, t_0+1]$

# Pure Aloha efficiency

---

$$\begin{aligned} P(\text{success by given node}) &= P(\text{node transmits}) \cdot \\ &\quad P(\text{no other node transmits in } [t_0-1, t_0]) \cdot \\ &\quad P(\text{no other node transmits in } [t_0, t_0+1]) \\ &= p \cdot (1-p)^{N-1} \cdot (1-p)^{N-1} \\ &= p \cdot (1-p)^{2(N-1)} \end{aligned}$$

... choosing optimum  $p$  and then letting  $n \rightarrow \infty$  ...

$$= 1/(2e) = .18$$

*even worse than slotted Aloha!*

# CSMA (Carrier Sense Multiple Access)

---

**CSMA**: listen before transmit:

If channel sensed idle: transmit entire frame

- ▶ If channel sensed busy, defer transmission

- ▶ human analogy: don't interrupt others!

# CSMA collisions

collisions *can still occur*:

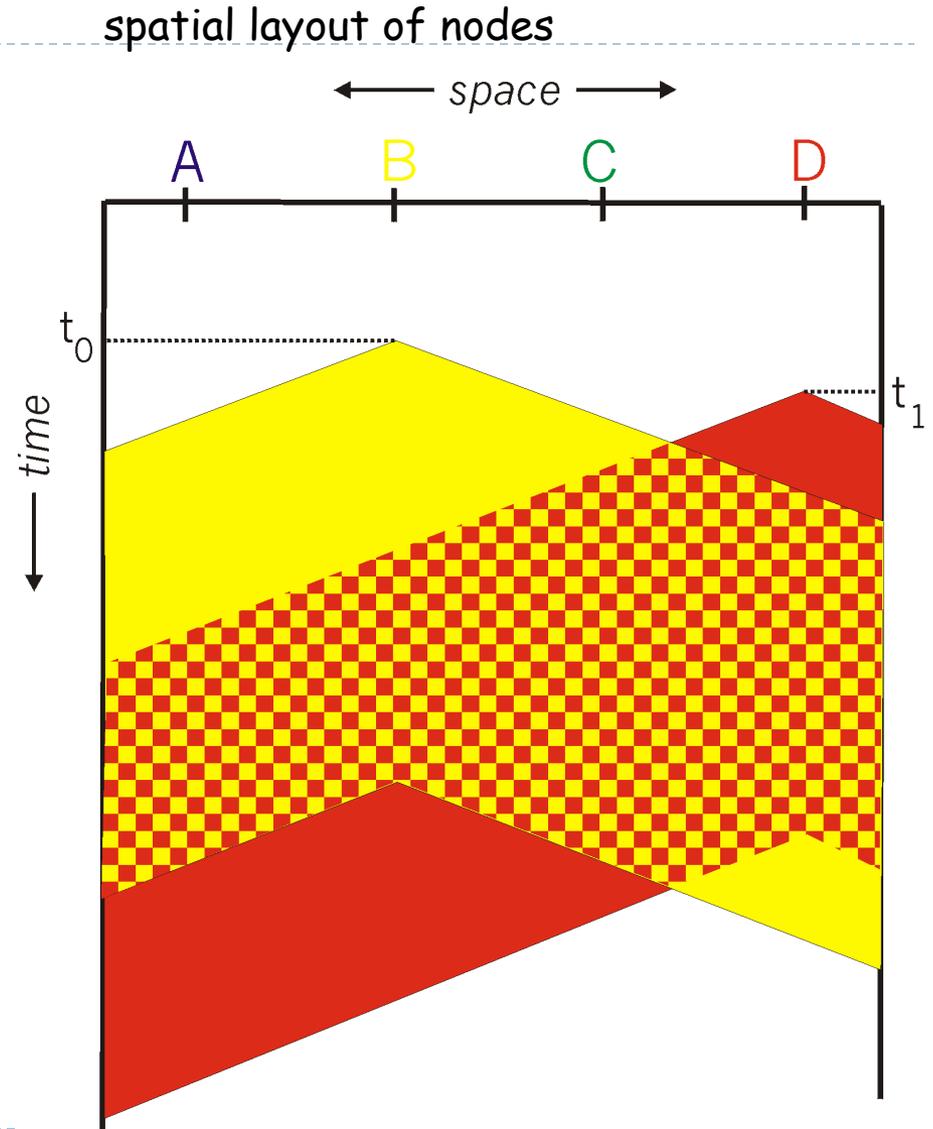

propagation delay means  
two nodes may not hear  
each other's transmission

collision:

entire packet transmission  
time wasted

note:

role of distance & propagation  
delay in determining collision  
probability  
"the longer the propagation  
delay, the larger the chance of  
collision"

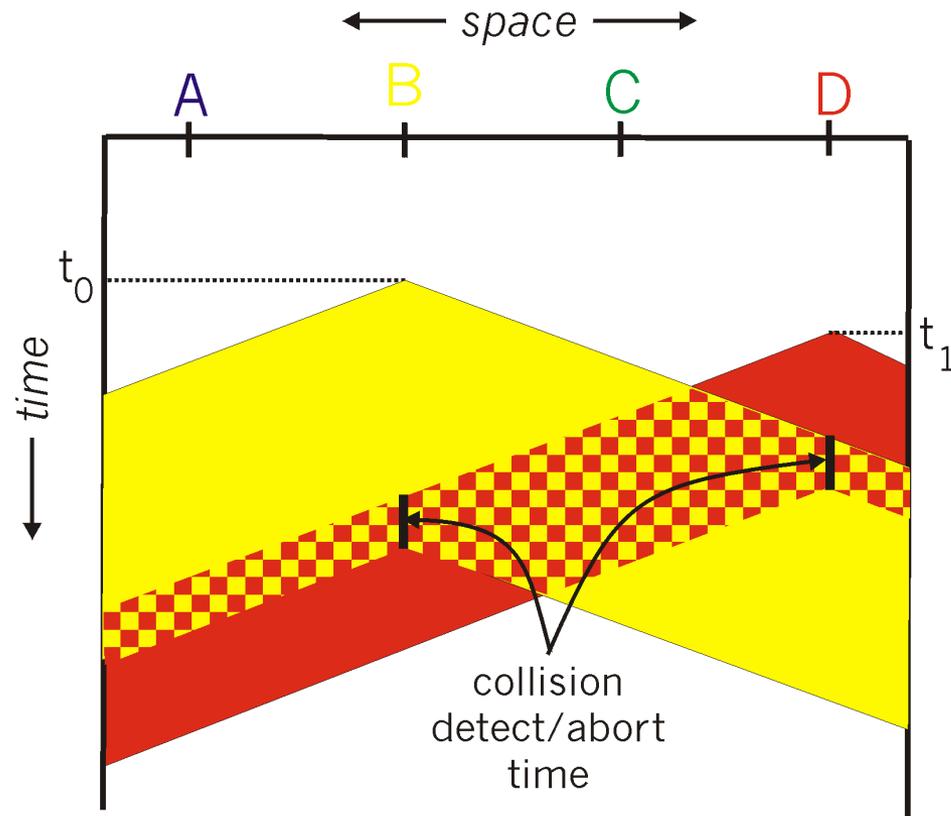

# CSMA/CD (Collision Detection)

---

**CSMA/CD:** carrier sensing, deferral as in CSMA

- ▶ collisions *detected* within short time
- ▶ colliding transmissions aborted, reducing channel wastage
- ▶ **collision detection:**
  - ▶ easy in wired LANs: measure signal strengths, compare transmitted, received signals
  - ▶ difficult in wireless LANs: received signal strength overwhelmed by local transmission strength
- ▶ **human analogy: the polite conversationalist**

# CSMA/CD collision detection

# “Taking Turns” MAC protocols

---

## channel partitioning MAC protocols:

- ▶ share channel *efficiently* and *fairly* at high load
- ▶ inefficient at low load: delay in channel access,  $1/N$  bandwidth allocated even if only 1 active node!

## Random access MAC protocols

- ▶ efficient at low load: single node can fully utilize channel
- ▶ high load: collision overhead

## “taking turns” protocols

look for best of both worlds!

*Remember the ideal requisites:*

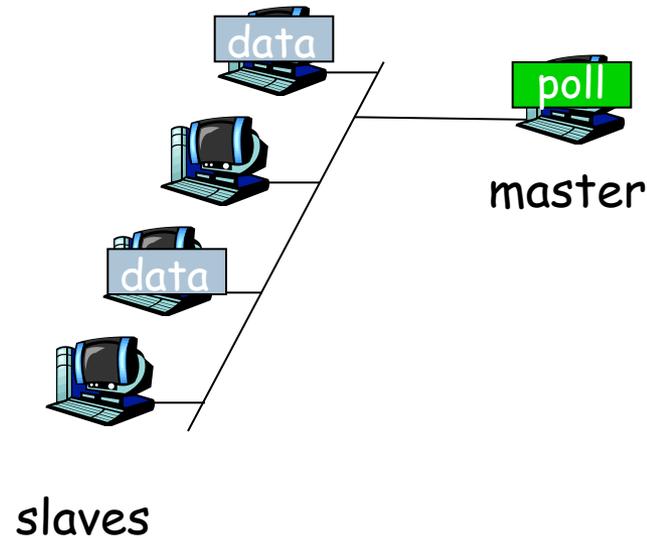

- 1) *Throughput =  $R$  bps when only one node has data to transmit*
- 2) *Throughput =  $R/M$  bps when  $M$  nodes have data to transmit*

# “Taking Turns” MAC protocols

---

## Polling:

- ▶ master node “invites” slave nodes to transmit in turn
- ▶ typically used with “dumb” slave devices
- ▶ concerns:
  - ▶ polling overhead
  - ▶ latency
  - ▶ single point of failure (master)

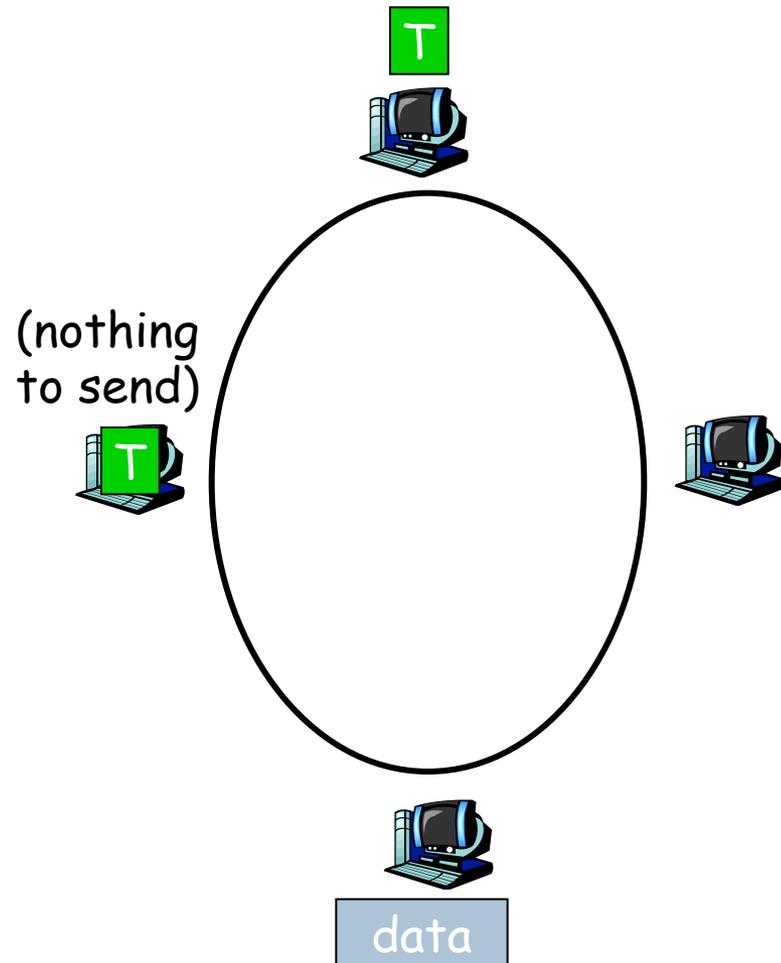

# “Taking Turns” MAC protocols

---

## Token passing:

- ❑ control **token** passed from one node to next sequentially.
- ❑ token message
- ❑ concerns:
  - token overhead
  - latency
  - single point of failure (token)

# Summary of MAC protocols

---

- ▶ **channel partitioning**, by time, frequency or code
  - ▶ Time Division, Frequency Division
- ▶ **random access** (dynamic),
  - ▶ ALOHA, S-ALOHA, CSMA, CSMA/CD
  - ▶ carrier sensing: easy in some technologies (wire), hard in others (wireless)
  - ▶ CSMA/CD used in Ethernet
  - ▶ CSMA/CA used in 802.11
- ▶ **taking turns**
  - ▶ polling from central site, token passing
  - ▶ Bluetooth, FDDI, IBM Token Ring

# Link Layer

---

- ▶ 5.1 Introduction and services
- ▶ 5.2 Error detection and correction
- ▶ 5.3 Multiple access protocols
- ▶ **5.4 Link-Layer Addressing**
- ▶ 5.5 Ethernet
- ▶ 5.6 Link-layer switches
- ▶ 5.7 PPP
- ▶ 5.8 Link virtualization: MPLS
- ▶ 5.9 A day in the life of a web request

# MAC Addresses and ARP

---

- ▶ **32-bit IP address:**

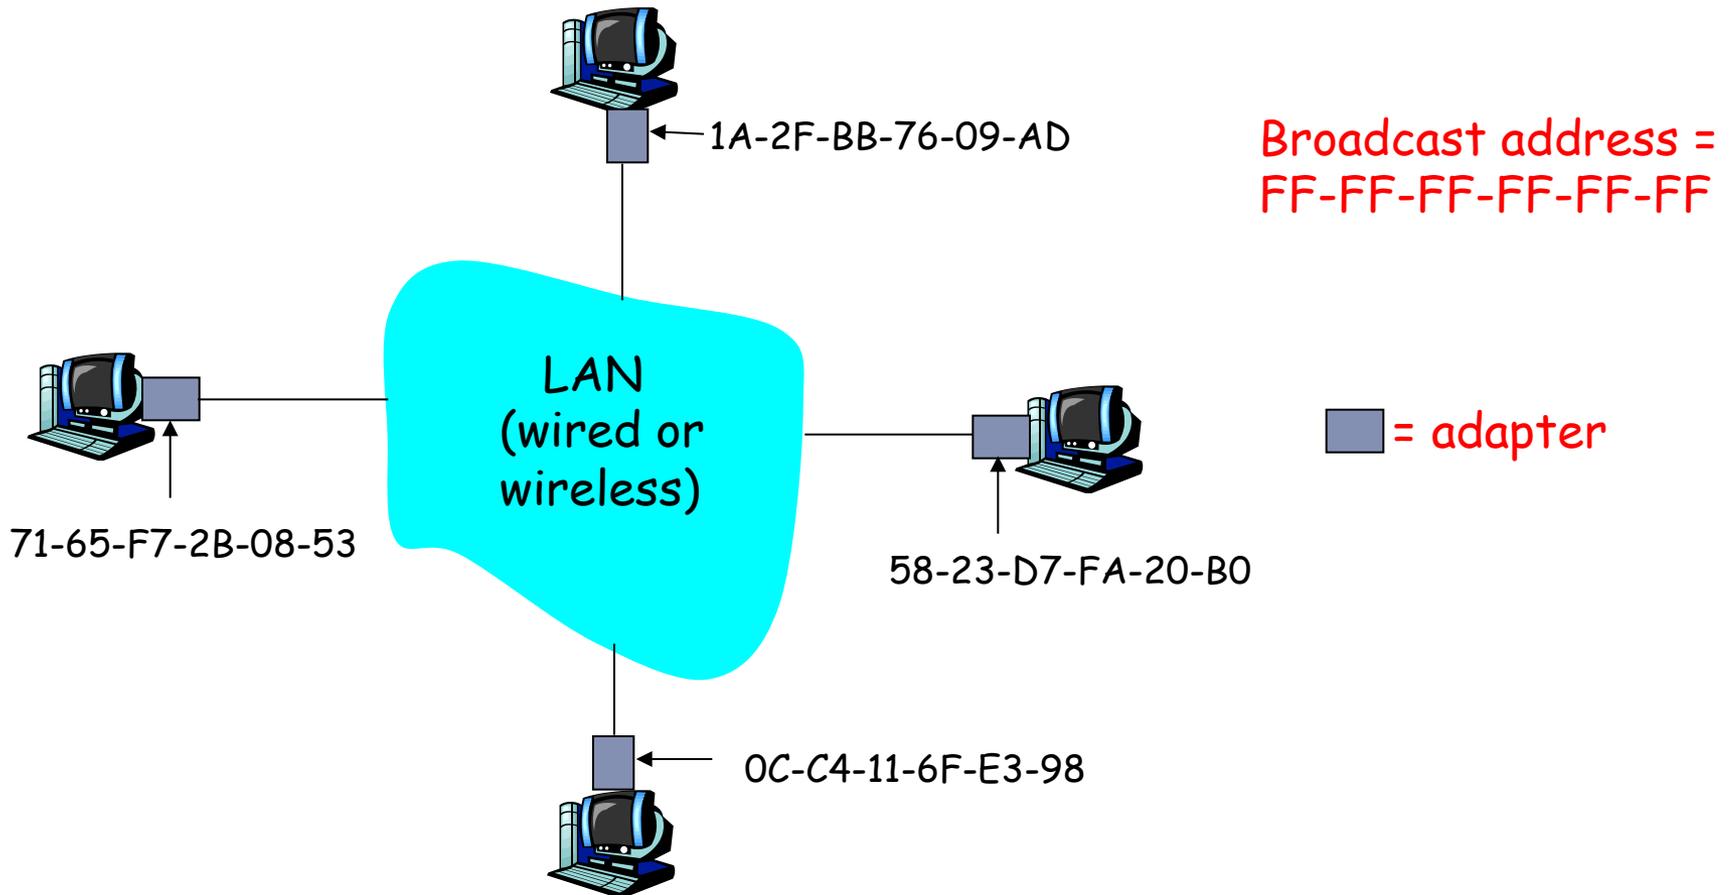

- ▶ *network-layer* address
- ▶ used to get datagram to destination IP subnet

- ▶ **MAC (or LAN or physical or Ethernet) address:**

- ▶ function: *get frame from one interface to another physically-connected interface (same network)*
- ▶ 48 bit MAC address (for most LANs)
  - ▶ 3 bytes for organization-specific prefix + 3 bytes to identify the card
  - ▶ burned in NIC ROM, also sometimes software settable

# LAN Addresses and ARP

Each adapter on LAN has unique LAN address

# LAN Address (more)

---

- ▶ MAC address allocation administered by IEEE
- ▶ manufacturer buys portion of MAC address space (to assure uniqueness)
- ▶ analogy:
  - (a) MAC address: like Social Security Number
  - (b) IP address: like postal address
- ▶ MAC flat address → portability
  - ▶ can move LAN card from one LAN to another
- ▶ IP hierarchical address NOT portable
  - ▶ address depends on IP subnet to which node is attached

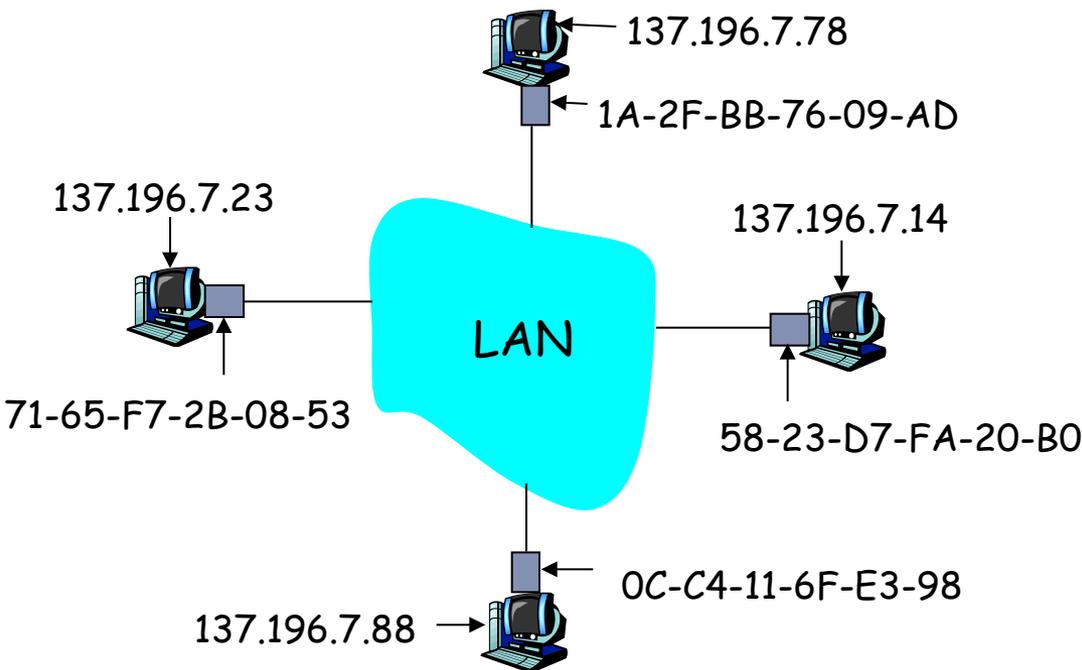

# ARP: Address Resolution Protocol

Question: how to determine MAC address of B knowing B's IP address?

- ▶ Each IP node (host, router) on LAN has **ARP** table
- ▶ ARP table: IP/MAC address mappings for some LAN nodes

< IP address; MAC address; TTL >

- ▶ TTL (Time To Live): time after which address mapping will be forgotten (typically 20 min)

# ARP protocol: Same LAN (network)

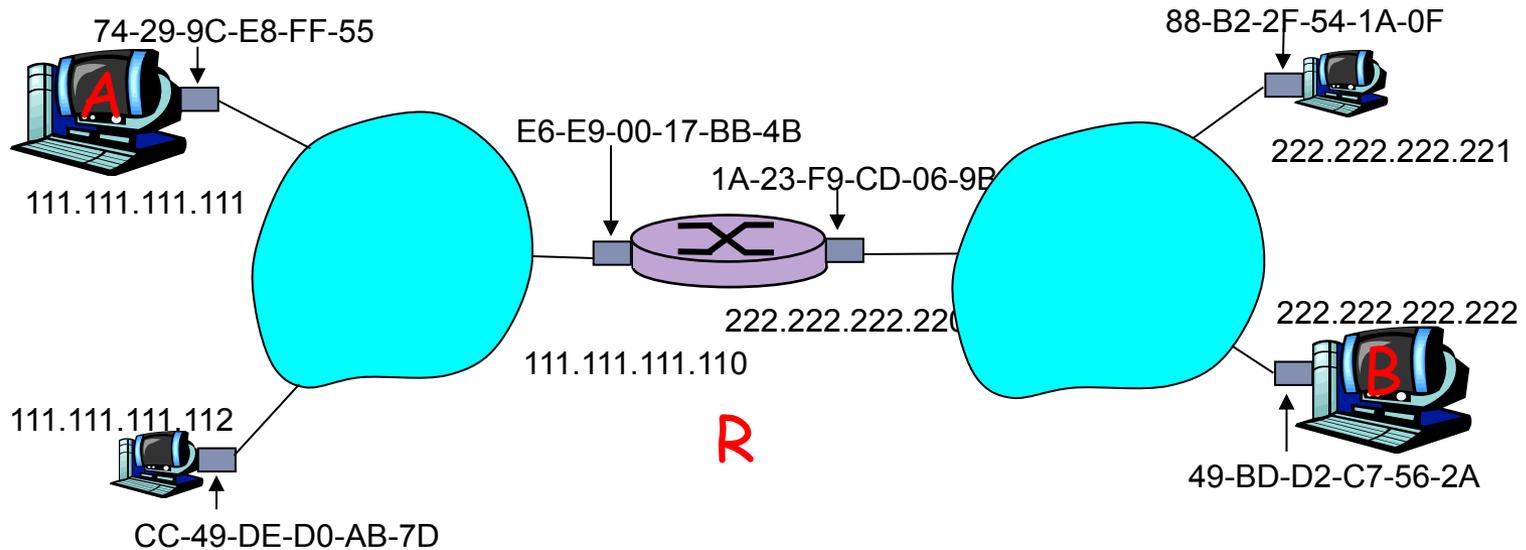

---

- ▶ A wants to send datagram to B, and B's MAC address not in A's ARP table.
- ▶ A **broadcasts** ARP query packet, containing B's IP address
  - ▶ dest MAC address = FF-FF-FF-FF-FF-FF
  - ▶ all machines on LAN receive ARP query
- ▶ B receives ARP packet, replies to A with its (B's) MAC address
  - ▶ frame sent to A's MAC address (unicast)
- ▶ A caches (saves) IP-to-MAC address pair in its ARP table until information becomes old (times out)
  - ▶ soft state: information that times out (goes away) unless refreshed
- ▶ ARP is “plug-and-play”:
  - ▶ nodes create their ARP tables *without intervention from net administrator*

# Addressing: routing to another LAN

walkthrough: **send datagram from A to B via R**

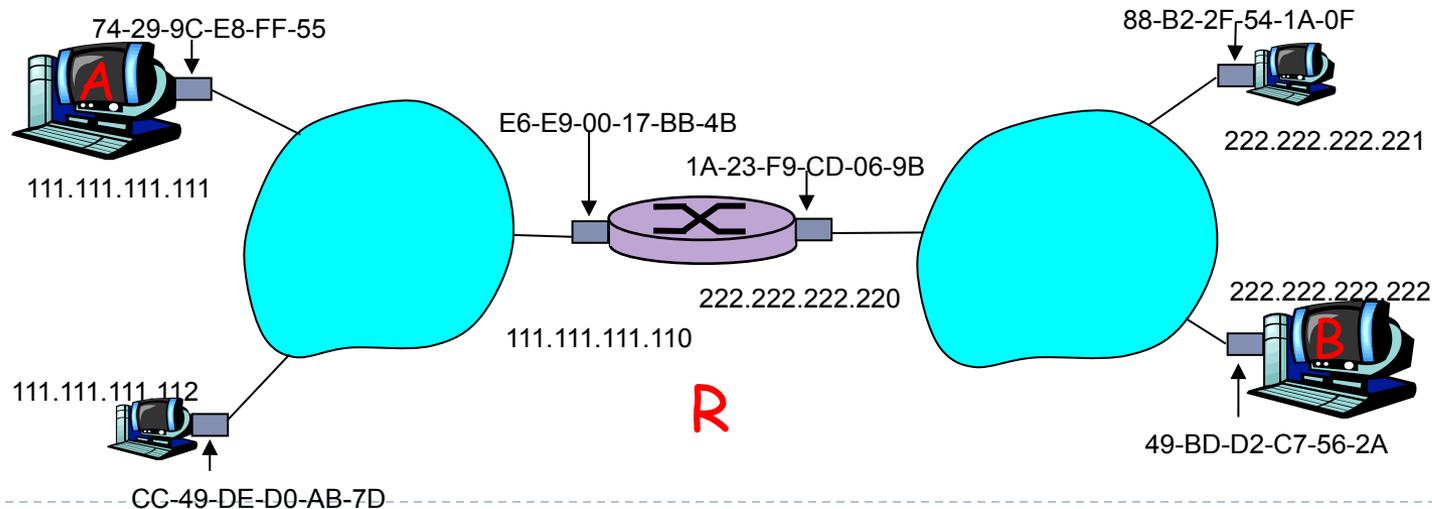

assume A knows B's IP address

- ▶ two ARP tables in router R, one for each IP network (LAN)

- ▶ A creates IP datagram with source A, destination B
  - ▶ A uses ARP to get R's MAC address for 111.111.111.110
- 
- ▶ A creates link-layer frame with R's MAC address as dest, frame contains A-to-B IP datagram
  - ▶ A's NIC sends frame
  - ▶ R's NIC receives frame
  - ▶ R removes IP datagram from Ethernet frame, sees its destined to B
  - ▶ R uses ARP to get B's MAC address
  - ▶ R creates frame containing A-to-B IP datagram sends to B

This is a **really** important example - make sure you understand!

# Link Layer

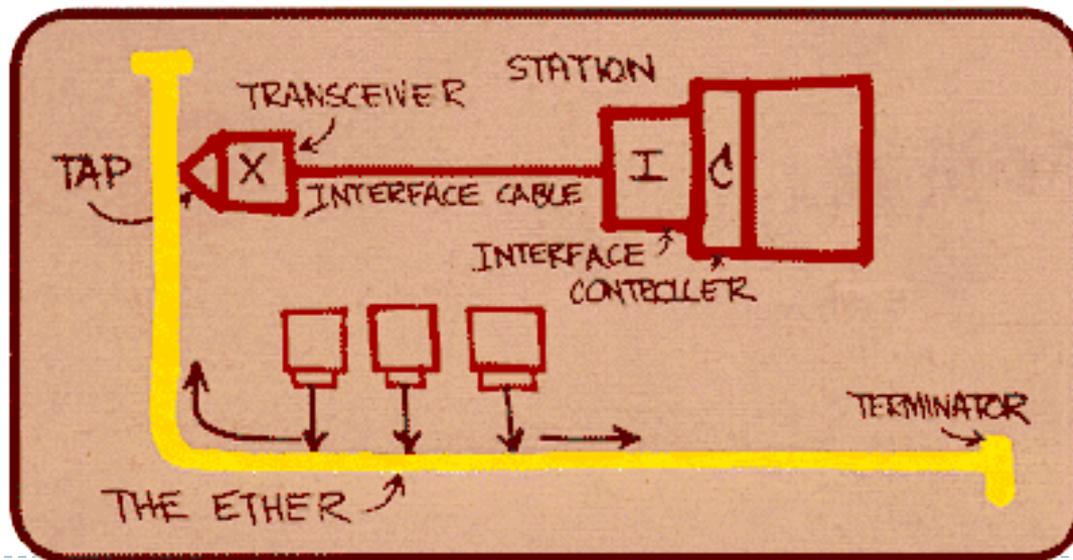

---

- ▶ 5.1 Introduction and services
- ▶ 5.2 Error detection and correction
- ▶ 5.3 Multiple access protocols
- ▶ 5.4 Link-Layer Addressing
- ▶ **5.5 Ethernet**
- ▶ 5.6 Link-layer switches
- ▶ 5.7 PPP
- ▶ 5.8 Link virtualization: MPLS
- ▶ 5.9 A day in the life of a web request

# Ethernet

“dominant” wired LAN technology:

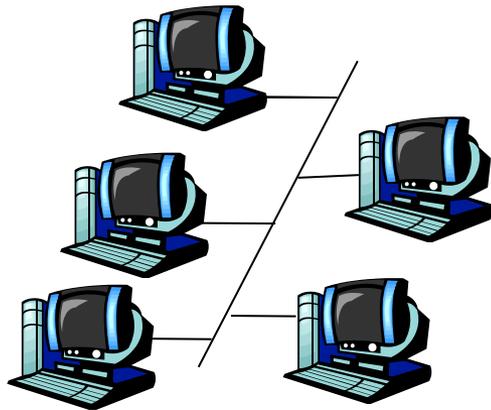

- ▶ cheap \$20 for NIC
- ▶ first widely used LAN technology
- ▶ simpler, cheaper than token LANs and ATM
- ▶ kept up with speed race: 10 Mbps – 10 Gbps

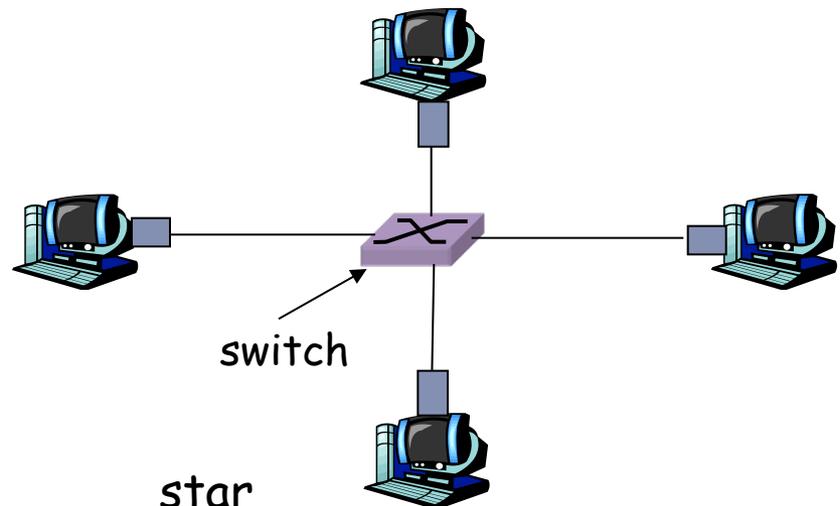

Metcalfe's Ethernet sketch

# Star topology\*\*\*

- ▶ bus topology popular through mid 90s
  - ▶ all nodes in same collision domain (can collide with each other)
- ▶ today: star topology prevails
  - ▶ active *switch* in center
  - ▶ each node runs a (separate) Ethernet protocol (nodes do not collide with each other)

bus: coaxial cable

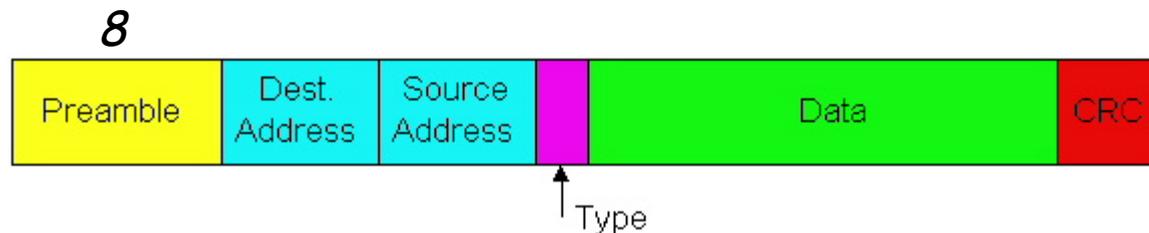

star

# Ethernet Frame Structure

---

Sending adapter encapsulates IP datagram (or other network layer protocol packet) in **Ethernet frame**

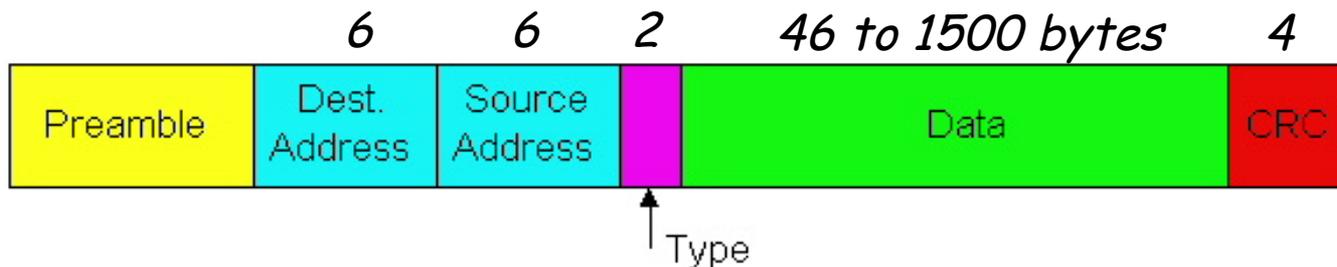

## Preamble:

- ▶ 7 bytes with pattern 10101010 followed by one byte with pattern 10101011
- ▶ used to synchronize receiver, sender clock rates

# Ethernet Frame Structure (more)

---

- ▶ **Addresses:** 6 bytes
  - ▶ if adapter receives frame with matching destination address, or with broadcast address (eg ARP packet), it passes data in frame to network layer protocol
  - ▶ otherwise, adapter discards frame
- ▶ **Type:** indicates higher layer protocol (mostly IP but others possible, e.g., Novell IPX, AppleTalk)
- ▶ **CRC:** checked at receiver, if error is detected, frame is dropped

# Ethernet: Unreliable, connectionless

---

- ▶ **connectionless**: No handshaking between sending and receiving NICs
- ▶ **unreliable**: receiving NIC doesn't send acks or nacks to sending NIC
  - ▶ stream of datagrams passed to network layer can have gaps (missing datagrams)
  - ▶ gaps will be filled if app is using TCP
  - ▶ otherwise, app will see gaps
- ▶ Ethernet's MAC protocol: unslotted **CSMA/CD**

# Ethernet CSMA/CD algorithm

---

1. NIC receives datagram from network layer, creates frame
2. - If NIC senses channel idle, starts frame transmission
  - If NIC senses channel busy, **waits until channel idle**, then transmits
3. If NIC transmits entire frame without detecting another transmission, NIC is **done** with frame !
4. If NIC detects another transmission while transmitting, aborts and sends **jam signal**
5. After aborting, NIC enters **exponential backoff**: after  $m$ th collision, NIC chooses  $K$  at random from  $\{0, 1, 2, \dots, 2^m - 1\}$  (max  $m=10$ ). NIC waits  $K \cdot 512$  bit times, returns to Step 2

# Ethernet's CSMA/CD (more)

---

**Jam Signal:** make sure all other transmitters are aware of collision; 48 bits

**Bit time:** .1 microsec for 10 Mbps Ethernet ;  
for  $K=1023$ , wait time is about 50 msec

## Exponential Backoff:

- ▶ *Goal:* adapt retransmission attempts to estimated current load
  - ▶ heavy load: random wait will be longer
- ▶ first collision: choose  $K$  from  $\{0,1\}$ ; delay is  $K \cdot 512$  bit transmission times
- ▶ after second collision: choose  $K$  from  $\{0,1,2,3\}$ ...
- ▶ after ten collisions, choose  $K$  from  $\{0,1,2,3,4,\dots,1023\}$

# CSMA/CD efficiency

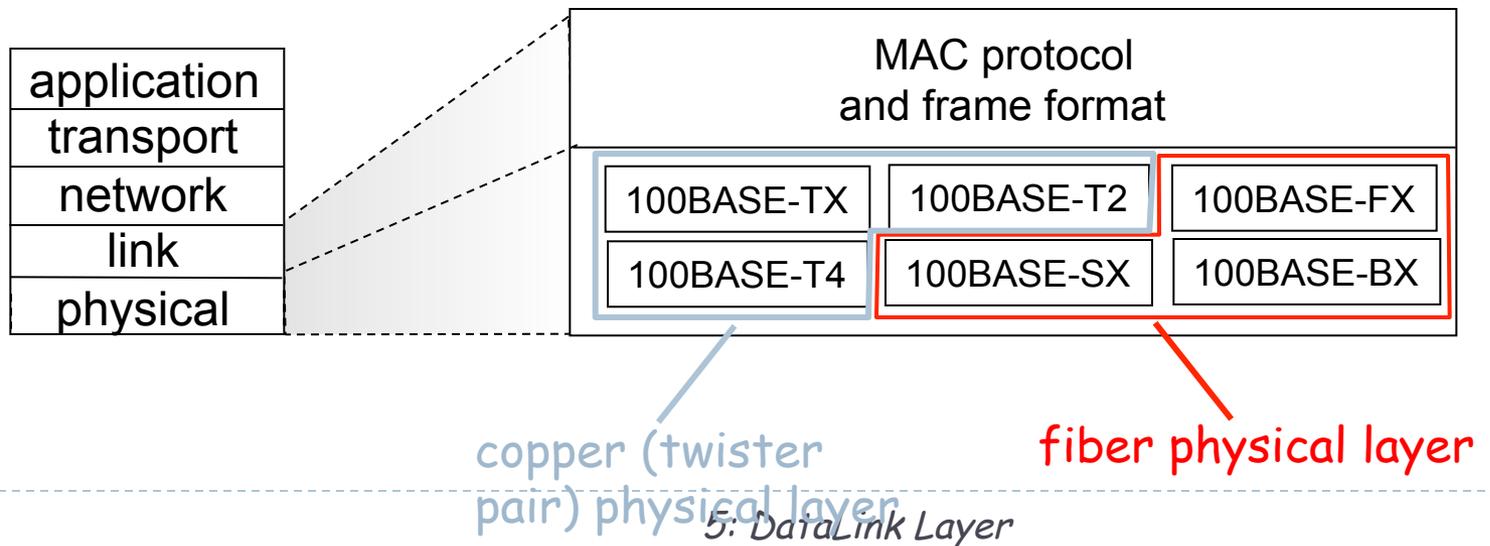

---

- ▶  $T_{\text{prop}}$  = max prop delay between 2 nodes in LAN
- ▶  $t_{\text{trans}}$  = time to transmit max-size frame
  
- ▶ efficiency goes to 1
  - ▶ as  $t_{\text{prop}}$  goes to 0
  - ▶ as  $t_{\text{trans}}$  goes to infinity
- ▶ better performance than ALOHA: and simple, cheap, decentralized!

$$\text{efficiency} = \frac{1}{1 + 5t_{\text{prop}}/t_{\text{trans}}}$$

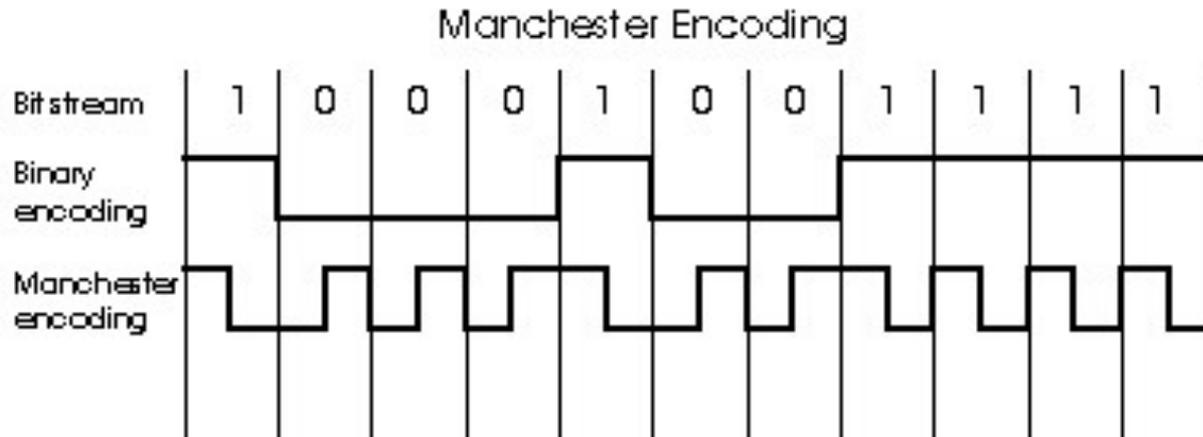

# 802.3 Ethernet Standards: Link & Physical Layers

- ▶ **many** different Ethernet standards
  - ▶ common MAC protocol and frame format
  - ▶ different speeds: 2 Mbps, 10 Mbps, 100 Mbps, 1 Gbps, 10G bps
  - ▶ different physical layer media: fiber, cable

# Manchester encoding

---

- ▶ used in 10BaseT
- ▶ each bit has a transition
- ▶ allows clocks in sending and receiving nodes to synchronize to each other
  - ▶ no need for a centralized, global clock among nodes!
- ▶ **Hey, this is physical-layer stuff!**

# Link Layer

---

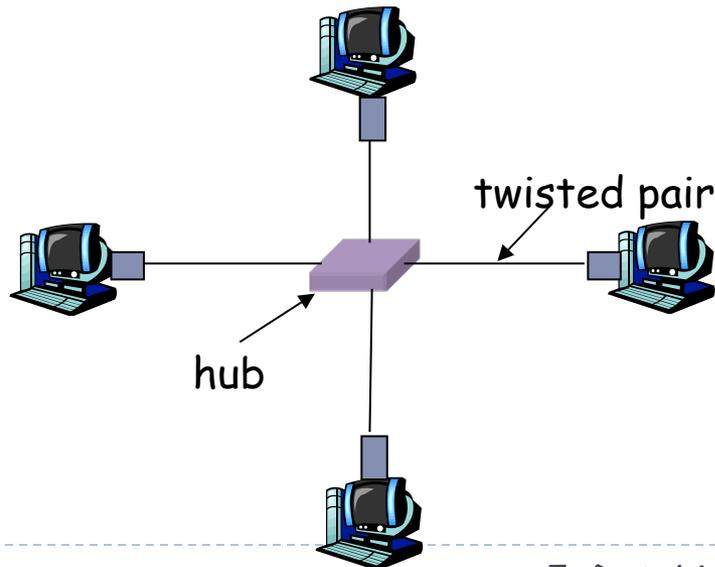

- ▶ 5.1 Introduction and services
- ▶ 5.2 Error detection and correction
- ▶ 5.3 Multiple access protocols
- ▶ 5.4 Link-layer Addressing
- ▶ 5.5 Ethernet
- ▶ 5.6 Link-layer switches, LANs, VLANs
- ▶ 5.7 PPP
- ▶ 5.8 Link virtualization: MPLS
- ▶ 5.9 A day in the life of a web request

# Hubs

---

... physical-layer (“dumb”) repeaters:

- ▶ bits coming in one link go out *all* other links at same rate
- ▶ all nodes connected to hub can collide with one another
- ▶ no frame buffering
- ▶ no CSMA/CD at hub: host NICs detect collisions

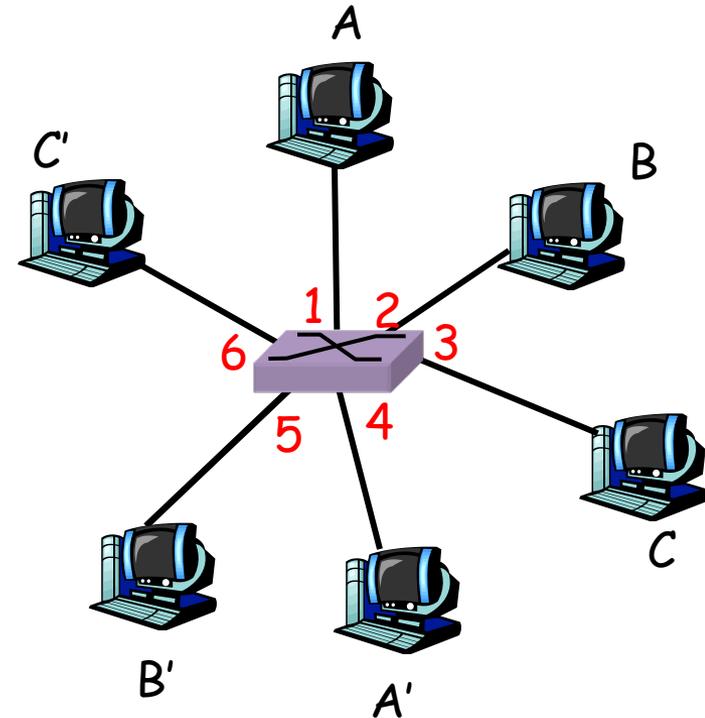

# Switch

---

- ▶ **link-layer device: smarter than hubs, take *active* role**
  - ▶ store, forward Ethernet frames
  - ▶ examine incoming frame's MAC address, **selectively** forward frame to one-or-more outgoing links when frame is to be forwarded on segment, uses CSMA/CD to access segment
- ▶ ***transparent***
  - ▶ hosts are unaware of presence of switches
- ▶ ***plug-and-play, self-learning***
  - ▶ switches do not need to be configured

# Switch: allows *multiple* simultaneous transmissions

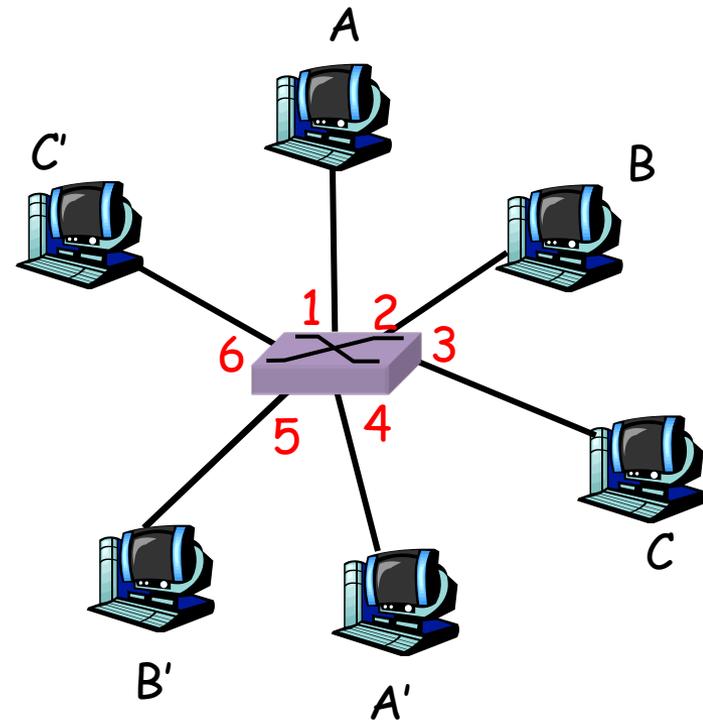

- ▶ hosts have dedicated, direct connection to switch
- ▶ switches buffer packets
- ▶ Ethernet protocol used on *each* incoming link, but no collisions; full duplex
  - ▶ each link is its own collision domain
- ▶ **switching**: A-to-A' and B-to-B' simultaneously, without collisions
  - ▶ not possible with dumb hub

*switch with six interfaces  
(1,2,3,4,5,6)*

# Switch Table

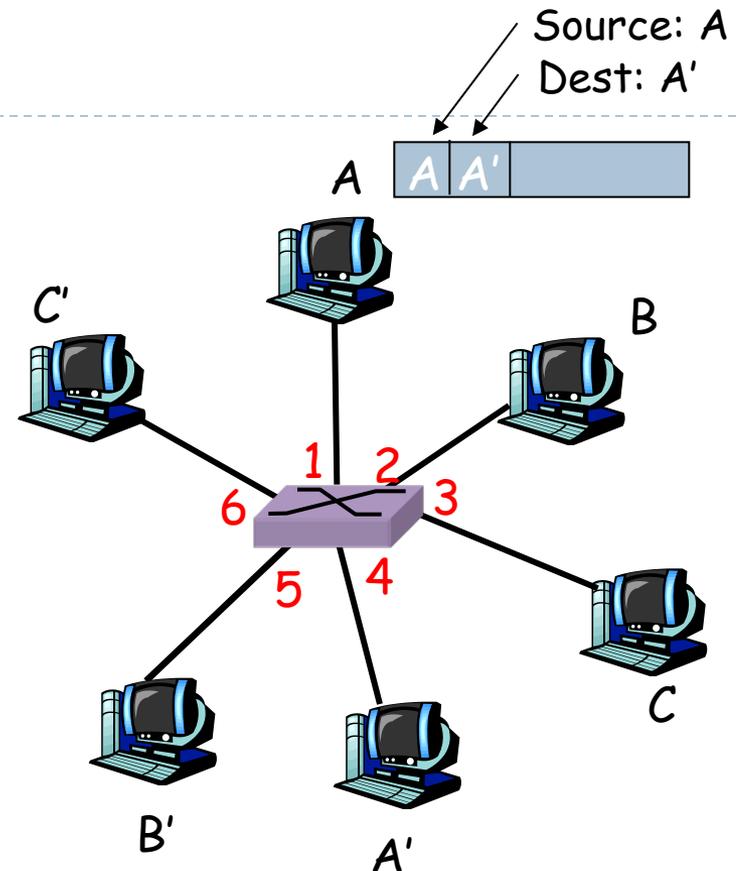

- ▶ **Q:** how does switch know that A' reachable via interface 4, B' reachable via interface 5?
- ▶ **A:** each switch has a **switch table**, each entry:
  - ▶ (MAC address of host, interface to reach host, time stamp)
- ▶ looks like a routing table!
- ▶ **Q:** how are entries created, maintained in switch table?
  - ▶ something like a routing protocol?

*switch with six interfaces  
(1,2,3,4,5,6)*

# Switch: self-learning

- ▶ switch *learns* which hosts can be reached through which interfaces
- ▶ when frame received, switch “learns” location of sender: incoming LAN segment
- ▶ records sender/location pair in switch table

MAC addr	interface	TTL
A	1	60

*Switch table  
(initially empty)*

# Switch: frame filtering/forwarding

---

## When frame received:

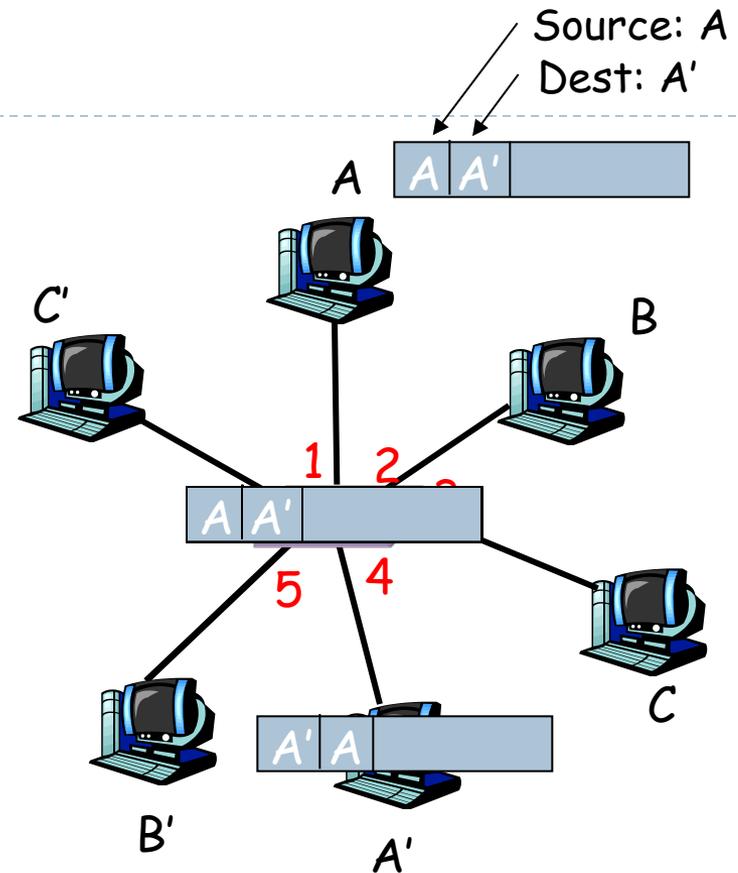

1. record link associated with sending host
2. index switch table using MAC dest address
3. **if** entry found for destination  
    **then** {  
        **if** dest on segment from which frame arrived  
            **then** drop the frame  
            **else** forward the frame on interface indicated  
        }  
    **else** flood

*forward on all but the interface  
on which the frame arrived*

# Self-learning, forwarding: example

- ▶ frame destination unknown: *flood*
- destination A location known: *selective send*

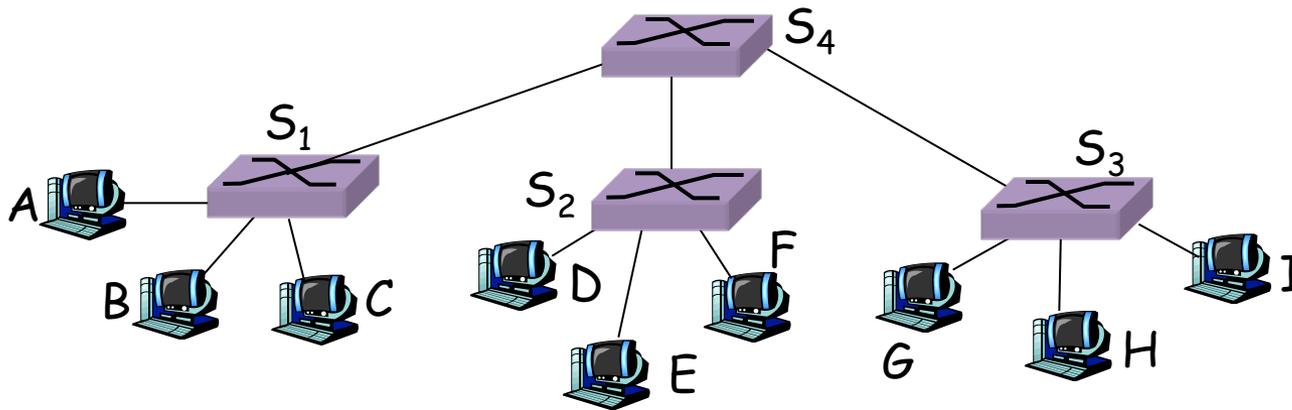

MAC addr	interface	TTL
A	1	60
A'	4	60

*Switch table  
(initially empty)*

# Interconnecting switches

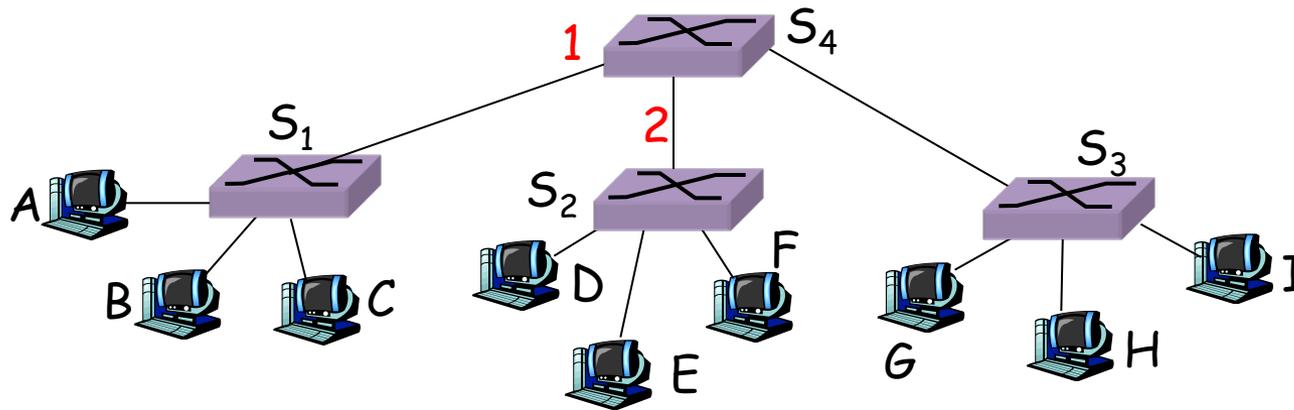

- ▶ switches can be connected together

- ❑ **Q:** sending from A to G - how does S<sub>1</sub> know to forward frame destined to F via S<sub>4</sub> and S<sub>3</sub>?
- ❑ **A:** self learning! (works exactly the same as in single-switch case!)

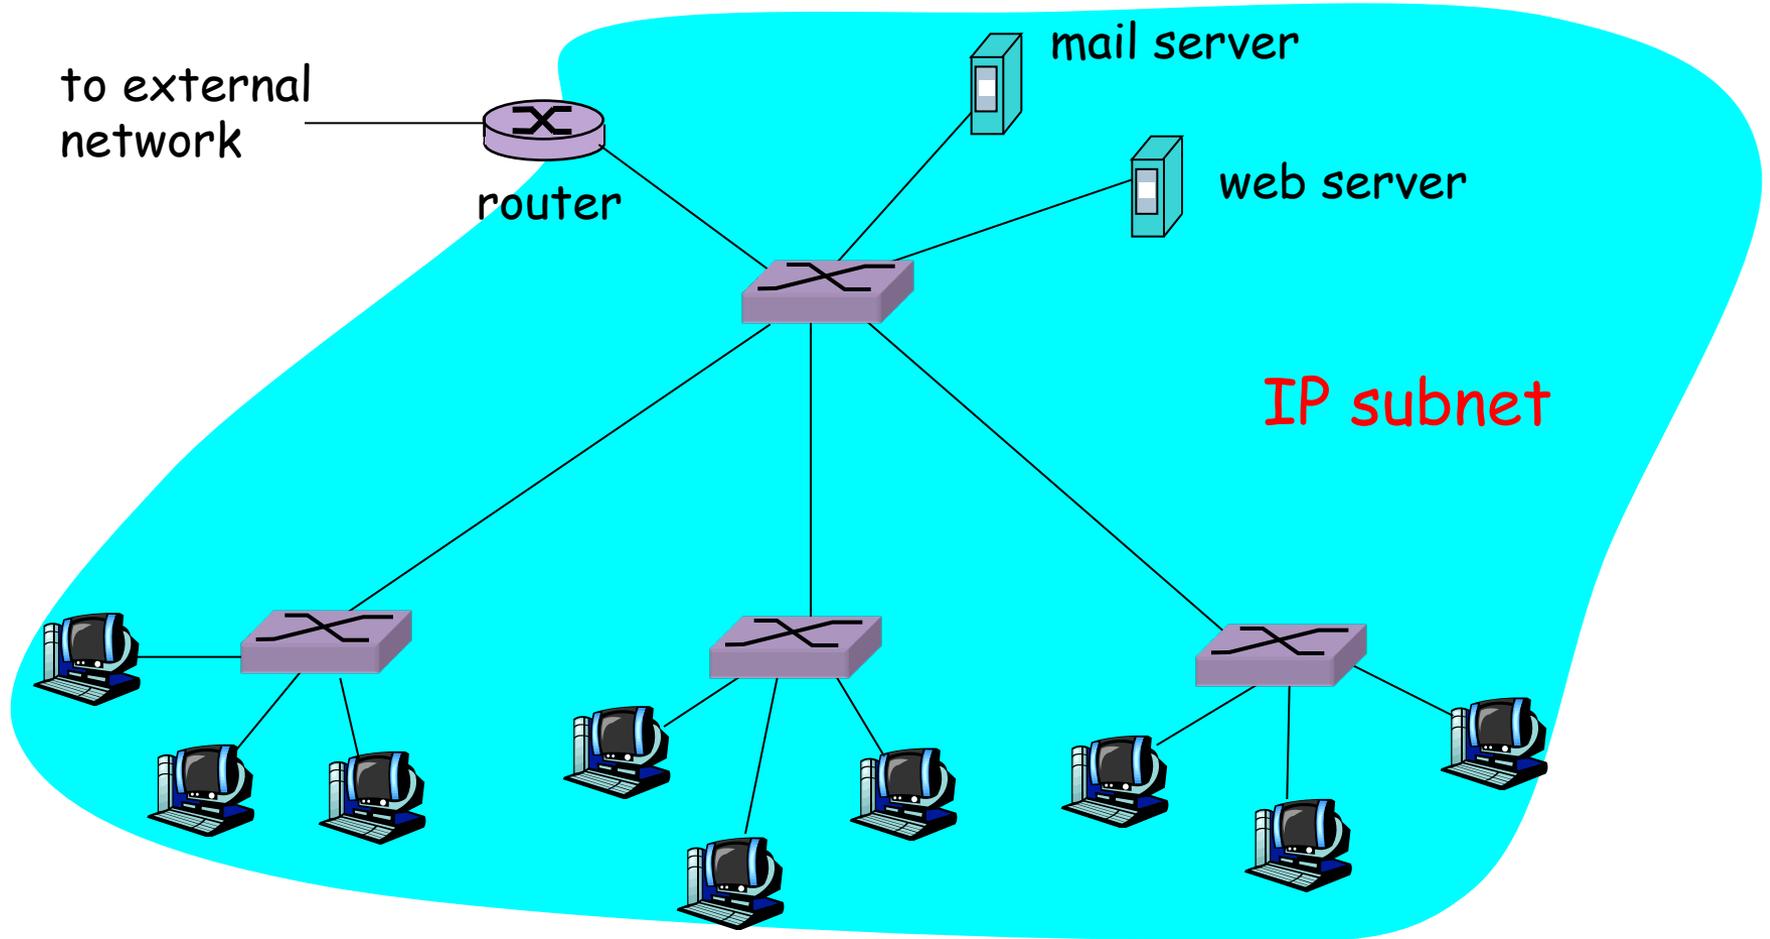

# Self-learning multi-switch example\*\*\*

Suppose C sends frame to I, I responds to C

- Q: show switch tables and packet forwarding in S<sub>1</sub>, S<sub>2</sub>, S<sub>3</sub>, S<sub>4</sub>

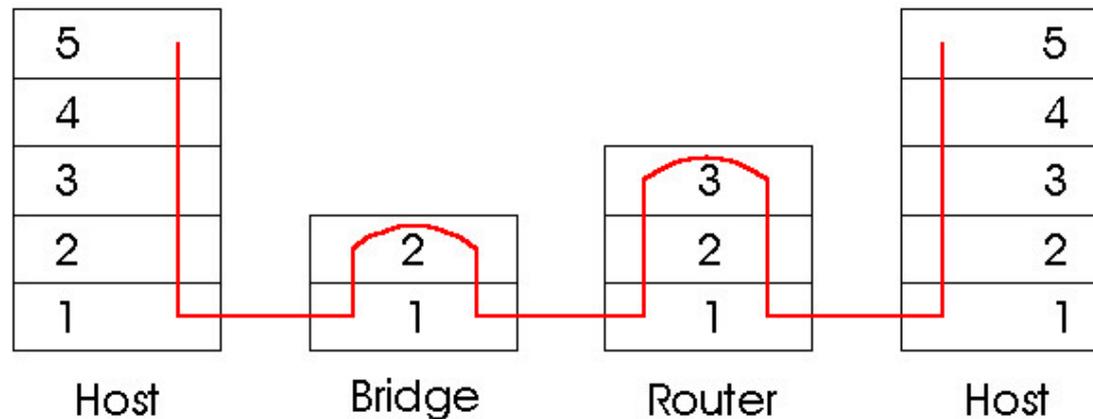

# Institutional network

# Switches vs. Routers

---

- ▶ both store-and-forward devices
  - ▶ routers: network layer devices (examine network layer headers)
  - ▶ switches are link layer devices
- ▶ routers maintain routing tables, implement routing algorithms
- ▶ switches maintain switch tables, implement filtering, learning algorithms

# Switch vs. ARP Poisoning

---

## ▶ Switch Poisoning

- ▶ Send Eth packets with spoofed src-MAC to the switch
- ▶ Objective: fill the MAC-to-NIC map
- ▶ Result: switch gets flooded, all frames will be *broadcasted* and therefore can be **sniffed!**

## ▶ ARP Poisoning

- ▶ Can be more targeted
- ▶ Objective: Poison the ARP table of a host X
- ▶ How? Attacker Y sends lots of spoofed ARP packets saying that the MAC address of the default gateway is actually Y's MAC
- ▶ Result: **Man-in-the-Middle Attack!**

# Link Layer

---

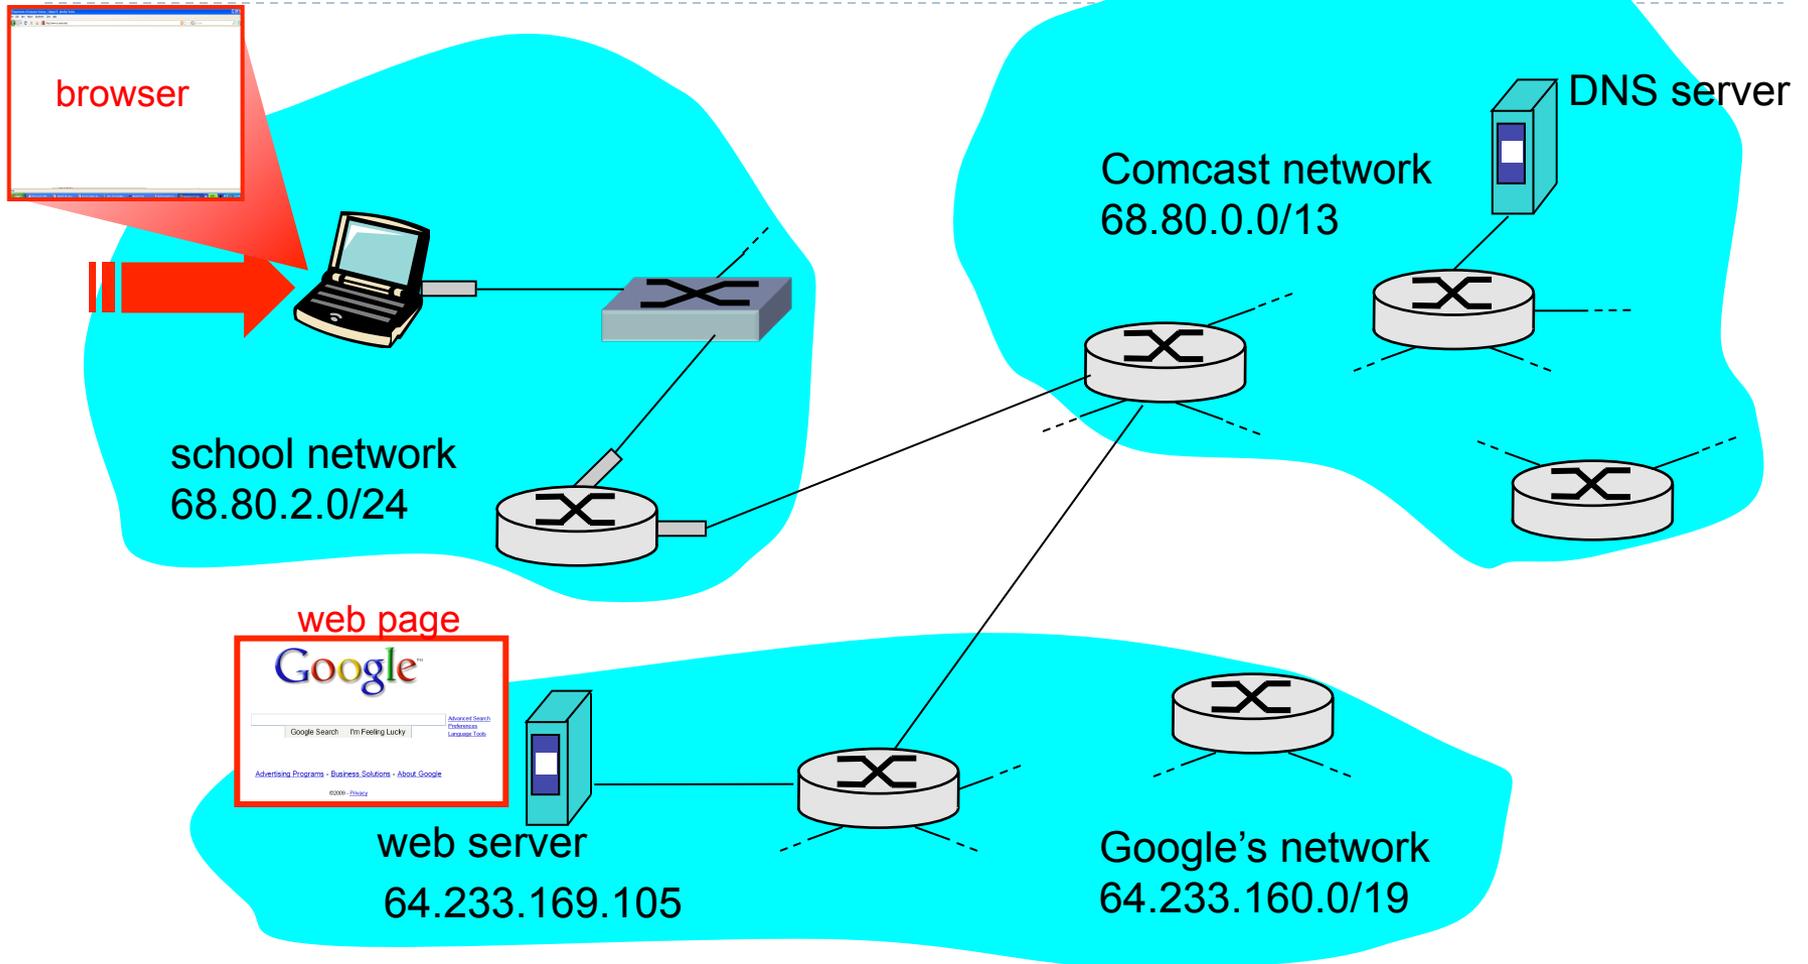

- ▶ 5.1 Introduction and services
- ▶ 5.2 Error detection and correction
- ▶ 5.3 Multiple access protocols
- ▶ 5.4 Link-Layer Addressing
- ▶ 5.5 Ethernet
- ▶ 5.6 Link-layer switches
- ▶ 5.7 PPP
- ▶ 5.8 Link virtualization: MPLS
- ▶ 5.9 A day in the life of a web request

# Synthesis: a day in the life of a web request

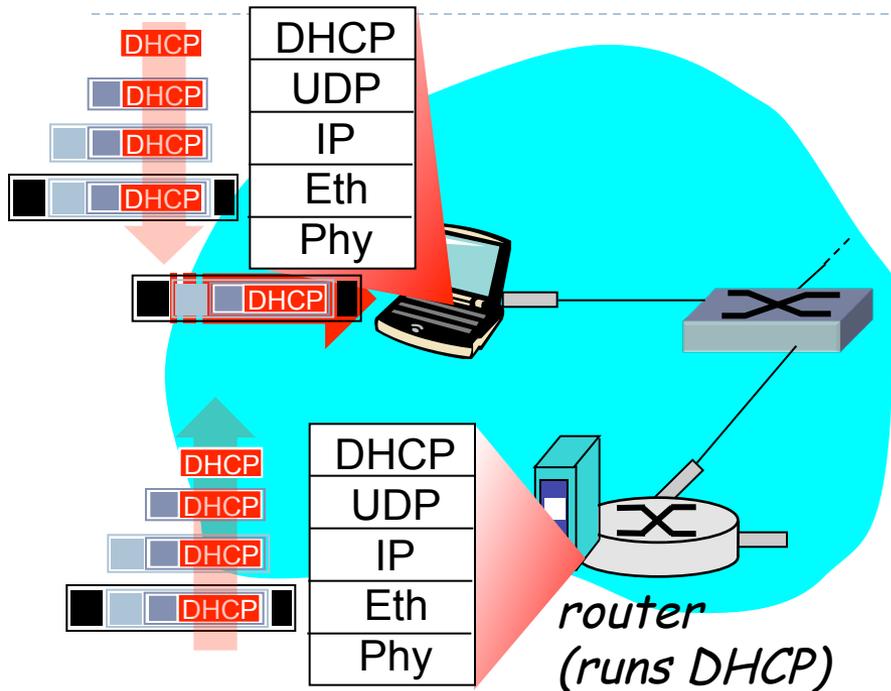

---

- ▶ journey down protocol stack complete!
  - ▶ application, transport, network, link
- ▶ putting-it-all-together: synthesis!
  - ▶ *goal*: identify, review, understand protocols (at all layers) involved in seemingly simple scenario: requesting www page
  - ▶ *scenario*: student attaches laptop to campus network, requests/receives www.google.com

# A day in the life: scenario

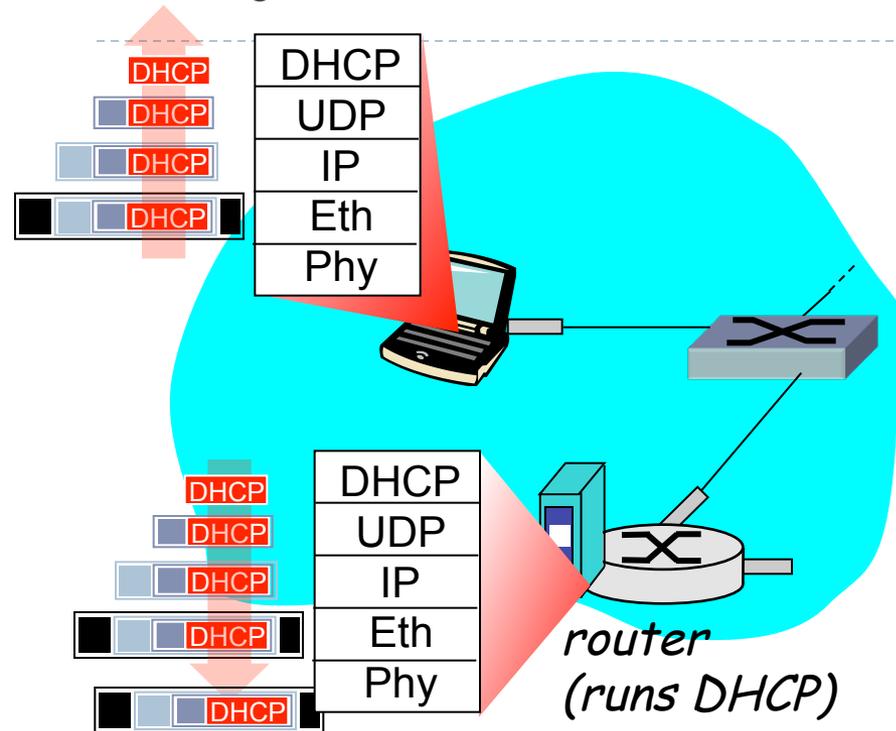

# A day in the life... connecting to the Internet

- ▶ connecting laptop needs to get its own IP address, addr of first-hop router, addr of DNS server: use **DHCP**
- DHCP request *encapsulated* in **UDP**, encapsulated in **IP**, encapsulated in **802.1** Ethernet
- Ethernet frame *broadcast* (dest: FFFFFFFFFFFFFFFF) on LAN, received at router running **DHCP** server
- Ethernet *demux'ed* to IP demux'ed, UDP demux'ed to DHCP

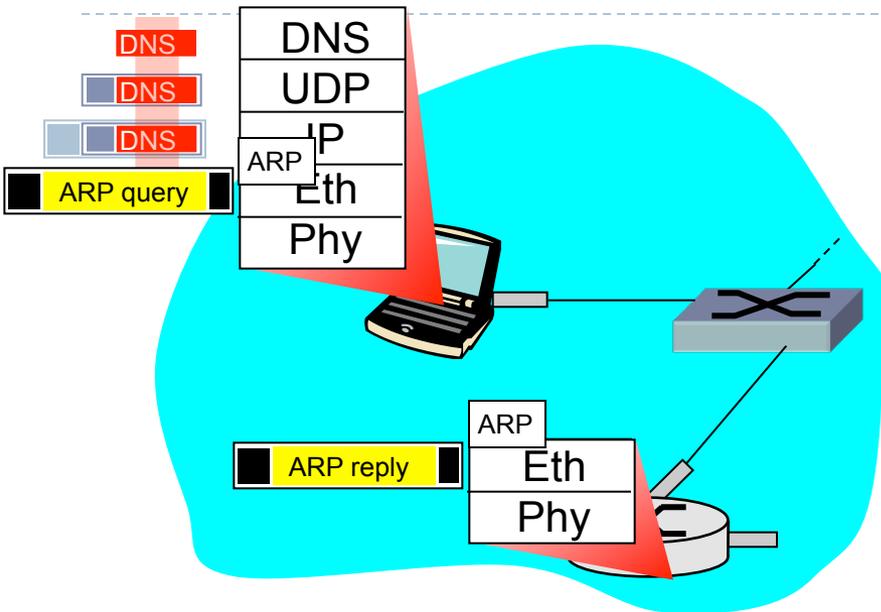

# A day in the life... connecting to the Internet

- ▶ DHCP server formulates **DHCP ACK** containing client's IP address, IP address of first-hop router for client, name & IP address of DNS server
- encapsulation at DHCP server, frame forwarded (*switch learning*) through LAN, demultiplexing at client
- DHCP client receives DHCP ACK reply

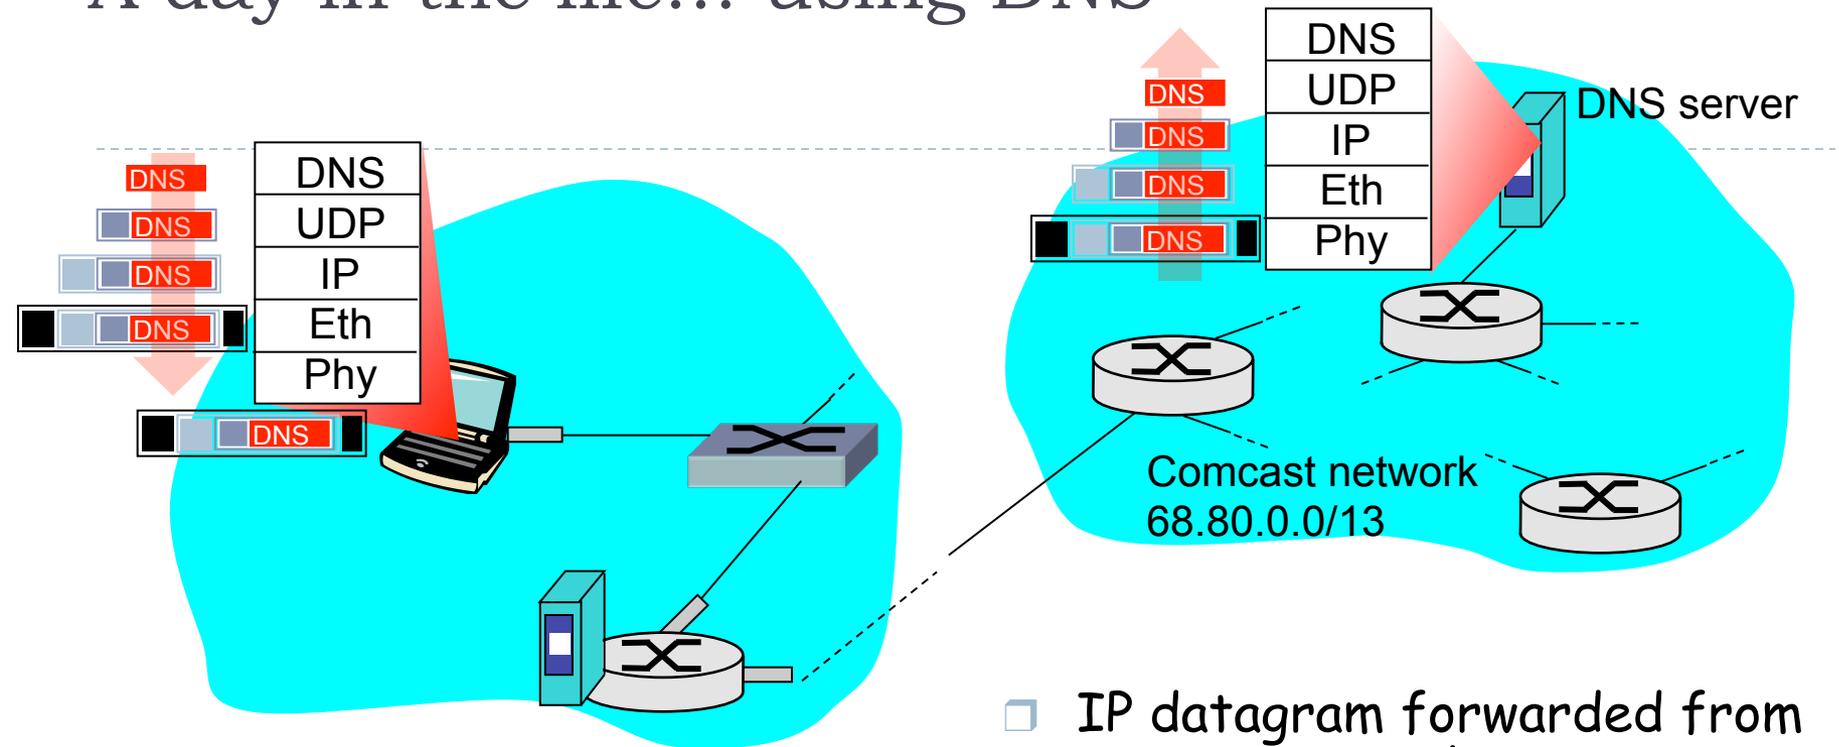

*Client now has IP address, knows name & addr of DNS server, IP address of its first-hop router*

# A day in the life... ARP (before DNS, before HTTP)

- ▶ before sending **HTTP** request, need IP address of `www.google.com`: **DNS**
- DNS query created, encapsulated in UDP, encapsulated in IP, encapsulated in Eth. In order to send frame to router, need MAC address of router interface: **ARP**
- **ARP query** broadcast, received by router, which replies with **ARP reply** giving MAC address of router interface
- client now knows MAC address of first hop router, so can now send frame containing DNS query

# A day in the life... using DNS

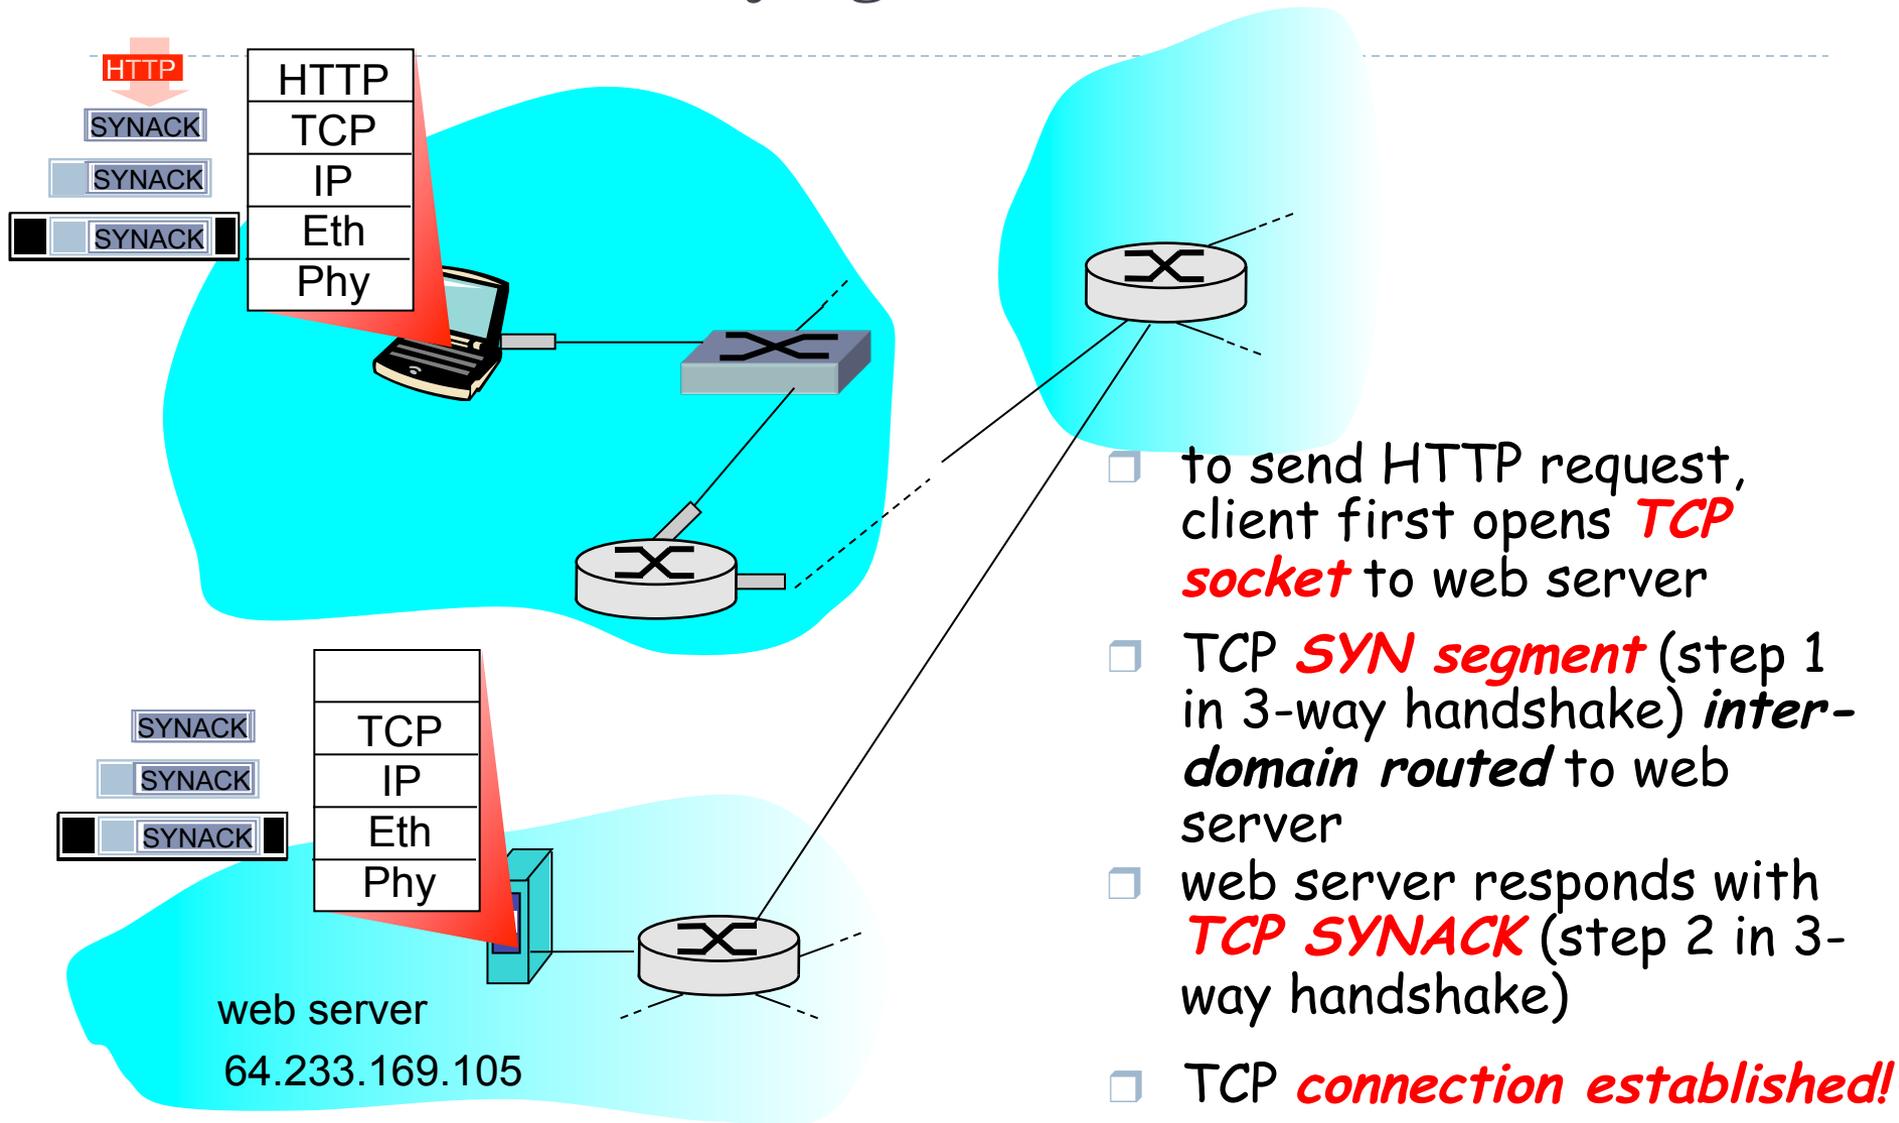

- ❑ IP datagram containing DNS query forwarded via LAN switch from client to 1<sup>st</sup> hop router

- ❑ IP datagram forwarded from campus network into comcast network, routed (tables created by **RIP**, **OSPF**, **IS-IS** and/or **BGP** routing protocols) to DNS server
- ❑ demux'ed to DNS server
- ❑ DNS server replies to client with IP address of

# A day in the life...

## TCP connection carrying HTTP

# A day in the life... HTTP request/reply
